1 Introduction

1.1 Description

The 3-Heights® PDF Extract API is a tool for extracting and querying various attributes and page content from a PDF document. This includes text, images, graphic objects, metadata, and embedded fonts, where some object types have additional properties to query. Configurable, intelligent mechanisms significantly increase extraction rates, for instance when extracting text.

1.2 Functions

The 3-Heights® PDF Extract API is used to extract text, images, and graphic objects, including paths from PDF documents. Text is extractable as lines and as individual words. It is also possible to query information such as position, color, font, and font size. Intelligent functions such as heuristics, word formation support, and character set interpretation make it possible to restore text that is lacking essential information. The tool can also collect significant data such as position, color space, and size when extracting images such as TIFF or JPEG. Querying document attributes such as PDF version, creator, author, title, subject, and creation date is also possible. The tool also supports reading encrypted PDF files.

1.2.1 Features

- Extract text:

- Extract word by word, with configurable word boundary detection
- Retrieve text attributes such as position, font and font size
- Automatically apply correct character decoding and produce Unicode output
- Extract raw character codes
- Extract graphics objects (paths):
 - Extract objects as strings that contain PDF graphics operators
 - Convert extracted paths to images
- Extract and store images:
 - Retrieve image attributes such as compression format, position, and transparency masks
 - Extract and store transparency masks
 - Extract and store alternate images
- Extract PDF document-level information:
 - Page count
 - PDF version
 - Page labels
 - Creation and modification date
 - Document information such as title, author, subjects, and more
 - Outlines (bookmarks), including destinations
- Extract page information:
 - Media box, crop box, trim box, bleed box, and art box
 - Page rotation
 - Annotations
- Extract and store embedded font files
- Retrieve detailed font information
- Retrieve optional content group (OCG) information and visibility (layers)
- Retrieve detailed graphic state information for each extracted page content object
- Extract raw PDF objects
- Extract document parts for PDF/X or PDF 2.0.
- Retrieve detailed color space information including lookup tables for indexed color spaces
- Extract and store embedded files
- Specify a password to decrypt PDF files

1.2.2 Formats

Input Formats:

- PDF 1.x (PDF 1.0, ..., PDF 1.7)
- PDF 2.0
- PDF/A-1, PDF/A-2, PDF/A-3

1.2.3 Conformance

Standards:

- ISO 32000-1 (PDF 1.7)
- ISO 32000-2 (PDF 2.0)
- ISO 19005-1 (PDF/A-1)
- ISO 19005-2 (PDF/A-2)
- ISO 19005-3 (PDF/A-3)

1.3 Interfaces

The following interfaces are available:

- C
- Java
- .NET Framework
- .NET Core¹
- COM

1.4 Operating systems

The 3-Heights® PDF Extract API is available for the following operating systems:

- Windows Client 7+ | x86 and x64
- Windows Server 2008, 2008 R2, 2012, 2012 R2, 2016, 2019, 2022 | x86 and x64
- Linux:
 - Red Hat, CentOS, Oracle Linux 7+ | x64
 - Fedora 29+ | x64
 - Debian 8+ | x64
 - Other: Linux kernel 2.6+, GCC toolset 4.8+ | x64
- macOS 10.10+ | x64

'+' indicates the minimum supported version.

1.5 How to best read this manual

If you are reading this manual for the first time and would like to evaluate the software, the following steps are suggested:

1. Read the [Introduction](#) chapter to verify this product meets your requirements.
2. Identify what interface your programming language uses.
3. Read and follow the instructions in [Installation and deployment](#).
4. In [Programming interfaces](#), find your programming language. Please note that not every language is covered in this manual.
For most programming languages, there is sample code available. To start, it is generally best to refer to these samples rather than writing code from scratch.
5. (Optional) Read the [User guide](#) for general information about the API. Read the [Interface reference](#) for specific information about the functions of the API.

¹ Limited supported OS versions. [Operating systems](#)

2 Installation and deployment

2.1 Windows

The 3-Heights® PDF Extract API comes as a ZIP archive or as a NuGet package.

To install the software, proceed as follows:

1. You need administrator rights to install this software.
2. Log in to your download account at <https://www.pdf-tools.com>. Select the product “PDF Extract API”. If you have no active downloads available or cannot log in, please contact pdfsales@pdf-tools.com for assistance.

You can find different versions of the product available. Download the version that is selected by default. You can select a different version.

The product comes as a [ZIP archive](#) containing all files, or as a [NuGet package](#) containing all files for development in .NET.

There is a 32 and a 64-bit version of the product available. While the 32-bit version runs on both 32 and 64-bit platforms, the 64-bit version runs on 64-bit platforms only. The ZIP archive as well as the NuGet package contain both the 32-bit and the 64-bit version of the product.

3. If you are using the ZIP archive, unzip the archive to a local folder, e.g. C:\Program Files\PDF Tools AG\.

This creates the following subdirectories (see also [ZIP archive](#)):

Subdirectory	Description
bin	Runtime executable binaries
doc	Documentation
include	Header files to include in your C/C++ project
jar	Java archive files for Java components
lib	Object file library to include in your C/C++ project
samples	Sample programs in various programming languages

4. The usage of the NuGet package is described in section [NuGet package](#).
5. (Optional) Register your license key using the [License management](#).
6. Identify the interface you are using. Perform the specific installation steps for that interface described in [Interface-specific installation steps](#).
7. Make sure your platform meets the requirements regarding color spaces described in [Color profiles](#).

2.2 Linux and macOS

This section describes installation steps required on Linux or macOS.

The Linux and macOS version of the 3-Heights® PDF Extract API provides two interfaces:

- Java interface
- Native C interface

Here is an overview of the files that come with the 3-Heights® PDF Extract API:

File description

Name	Description
bin/x64/libPdfParser.so	Shared library that contains the main functionality. The file's extension differs on macOS, (.dylib instead of .so).
doc/*.*	Documentation
include/*.h	Header files to include in your C/C++ project
jar/EXPA.jar	Java API archive
samples	Example code

2.2.1 Linux

1. Unpack the archive in an installation directory, e.g. /opt/pdf-tools.com/
2. Verify that the GNU shared libraries required by the product are available on your system:

```
ldd libPdfParser.so
```

If the previous step reports any missing libraries, you have two options:

- a. Download an archive that is linked to a different version of the GNU shared libraries and verify whether they are available on your system. Use any version whose requirements are met. Note that this option is not available for all platforms.
 - b. Use your system's package manager to install the missing libraries. It usually suffices to install the package `libstdc++6`.
3. Create a link to the shared library from one of the standard library directories, e.g.

```
ln -s /opt/pdf-tools.com/bin/x64/libPdfParser.so /usr/lib
```

4. Optionally, register your license key using the [license manager](#).
5. Identify the interface you are using. Perform the specific installation steps for that interface described in [Interface-specific installation steps](#).
6. Make sure your platform meets the requirements regarding color spaces described in [Color profiles](#).

2.2.2 macOS

The shared library must have the extension `.jnilib` for use with Java. Create a file link for this purpose by using the following command:

```
ln libPDFParser.dylib libPDFParser.jnilib
```

2.3 ZIP archive

The 3-Heights® PDF Extract API provides four different interfaces. The installation and deployment of the software depend on the interface you are using. The table below shows the supported interfaces and some of the programming languages that can be used.

Interface	Programming languages
.NET	<p>The MS software platform .NET can be used with any .NET capable programming language such as:</p> <ul style="list-style-type: none"> ■ C# ■ VB .NET ■ J# ■ others <p>For a convenient way to use this interface, see NuGet package.</p>
Java	The Java interface is available on all platforms.
COM	<p>The component object model (COM) interface can be used with any COM-capable programming language, such as:</p> <ul style="list-style-type: none"> ■ MS Visual Basic ■ MS Office Products such as Access or Excel (VBA) ■ C++ ■ VBScript ■ others <p>This interface is available in the Windows version only.</p>
C	The native C interface is for use with C and C++. This interface is available on all platforms.

2.3.1 Development

The software development kit (SDK) contains all files that are used for developing the software. The role of each file in each of the four different interfaces is shown in table [Files for development](#). The files are split in four categories:

Req. The file is required for this interface.

Opt. The file is optional. See also the [File description](#) table to identify the files are required for your application.

Doc. The file is for documentation only.

Empty field An empty field indicates this file is not used for this particular interface.

Files for development

Name	.NET	Java	COM	C
bin\<platform>\PDFParser.dll	Req.	Req.	Req.	Req.
bin*NET.dll	Req.			
bin*NET.xml	Doc.			
doc*.pdf	Doc.	Doc.	Doc.	Doc.
doc\PDFParser.idl			Doc.	
doc\javadoc*.*		Doc.		

Files for development

Name	.NET	Java	COM	C
include\expa_c.h				Req.
include*.*				Opt.
jar\EXPA.jar		Req.		
lib\<platform>\PDFParser.lib				Req. ²
samples*.*	Doc.	Doc.	Doc.	Doc.

The purpose of the most important distributed files is described in the [File description](#) table.

File description

Name	Description
bin\<platform>\PDFParser.dll	DLL that contains the main functionality (required), where <platform> is either Win32 or x64 for the 32-bit or the 64-bit library, respectively.
bin*NET.dll	.NET assemblies are required when using the .NET interface. The files bin*NET.xml contain the corresponding XML documentation for MS Visual Studio.
doc*.*	Documentation
include*.*	Files to include in your C / C++ project
lib\<platform>\PDFParser.lib	On Windows operating systems, the object file library needs to be linked to the C/C++ project.
jar\EXPA.jar	Java API archive
samples*.*	Sample programs in different programming languages

2.3.2 Deployment

For the deployment of the software, only a subset of the files are required. The table below shows the files that are required (Req.), optional (Opt.) or not used (empty field) for the four different interfaces.

Files for deployment

Name	.NET	Java	COM	C
bin\<platform>\PDFParser.dll	Req.	Req.	Req.	Req.

² Not required for Linux or macOS.

³ These files must reside in the same directory as PDFParser.dll.

Files for deployment

bin*NET.dll	Req.
jar\EXPA.jar	Req.

The deployment of an application works as described below:

1. Identify the required files from your developed application (this may also include color profiles).
2. Identify all files that are required by your developed application.
3. Include all these files in an installation routine such as an MSI file or a simple batch script.
4. Perform any interface-specific actions (e.g. registering when using the COM interface).

Example: This is a very simple example of how a COM application written in Visual Basic 6 could be deployed.

1. The developed and compiled application consists of the file `TextExt.exe`. Color profiles are not used.
2. The application uses the COM interface and is distributed on Windows only.
 - The main DLL `PDFParser.dll` must be distributed.
3. All files are copied to the target location using a batch script. This script contains the following commands:

```
copy TextExt.exe %targetlocation%\.  
copy PDFParser.dll %targetlocation%\.
```

4. For COM, the main DLL needs to be registered in silent mode (`/s`) on the target system. This step requires Power-User privileges and is added to the batch script.

```
regsvr32 /s %targetlocation%\PDFParser.dll.
```

2.4 NuGet package

NuGet is a package manager that lets you integrate libraries for software development in .NET. The NuGet package for the 3-Heights® PDF Extract API contains all the libraries needed, both managed and native.

Installation

The package `PdfTools.PDFParser 6.27.2` is available on nuget.org. Right-click on your .NET project in Visual Studio and select "Manage NuGet Packages...". Finally, select the package source "nuget.org" and navigate to the package `PdfTools.PDFParser 6.27.2`.

Development

The package `PdfTools.PDFParser 6.27.2` contains .NET libraries with versions .NET Standard 1.1, .NET Standard 2.0, and .NET Framework 2.0, and native libraries for Windows, macOS, and Linux.

The required native libraries are loaded automatically. All project platforms are supported, including "AnyCPU".

To use the software, you must first install a license key for the 3-Heights® PDF Extract API. To do this, you have to download the product kit and use the license manager in it. See also [License management](#).

Note: This NuGet package is only supported on a subset of the operating systems supported by .NET Core. See also [Operating systems](#).

2.5 Interface-specific installation steps

2.5.1 COM interface

Registration

Before you can use the 3-Heights® PDF Extract API component in your COM application program, you have to register the component using the `regsvr32.exe` program that is provided with the Windows operating system. The following command shows how to register the `PDFParser.dll`. In Windows Vista and later, the command needs to be executed from an administrator shell.

```
regsvr32 "C:\Program Files\PDF Tools AG\bin\<platform>\PDFParser.dll"
```

Where `<platform>` is `Win32` for the 32-bit and `x64` for the 64-bit version.

If you are using a 64-bit operating system and would like to register the 32-bit version of the 3-Heights® PDF Extract API, you need to use the `regsvr32` from the directory `%SystemRoot%\SysWOW64` instead of `%SystemRoot%\System32`.⁴

If the registration process succeeds, a corresponding dialog window is displayed. The registration can also be done silently (e.g. for deployment) using the switch `/s`.

Other files

The other DLLs do not need to be registered, but for simplicity, it is suggested that they reside in the same directory as the `PDFParser.dll`.

2.5.2 Java interface

The 3-Heights® PDF Extract API requires Java version 7 or higher.

For compilation and execution

When using the Java interface, the Java wrapper `jar\EXPA.jar` needs to be on the CLASSPATH. You can do this by either adding it to the environment variable CLASSPATH, or by specifying it using the switch `-classpath`:

```
javac -classpath ".;C:\Program Files\PDF Tools AG\jar\EXPA.jar" ^
sampleApplication.java
```

For execution

Additionally, the library `PDFParser.dll` needs to be in one of the system's library directories⁵ or added to the Java system property `java.library.path`. You can add the library by either adding it dynamically at program startup before using the API, or by specifying it using the switch `-Djava.library.path` when starting the Java VM. Choose the correct subdirectory (`x64` or `Win32` on Windows) depending on the platform of the Java VM⁶.

⁴ Otherwise, you get the following message: `LoadLibrary("PDFParser.dll") failed - The specified module could not be found.`

⁵ On Windows defined by the environment variable `PATH`, and on Linux defined by `LD_LIBRARY_PATH`.

⁶ If the wrong data model is used, there is an error message similar to this: `"Can't load IA 32-bit .dll on a AMD 64-bit platform"`

```
java -classpath ".;C:\Program Files\PDF Tools AG\EXPA.jar" ^  
"-Djava.library.path=C:\Program Files\PDF Tools AG\bin\x64" sampleApplication
```

On Linux or macOS, the path separator usually is a colon and hence the above changes to something like:

```
... -classpath ".:path/to/EXPA.jar" ...
```

2.5.3 .NET interface

The 3-Heights® PDF Extract API does not provide a pure .NET solution. Instead, it consists of a native library and .NET assemblies, which call the native library. This has to be accounted for when installing and deploying the tool.

It is recommended that you use the [NuGet package](#). This ensures the correct handling of both the .NET assemblies and the native library.

Alternatively, the files in the [ZIP archive](#) can be used directly in a Visual Studio project targeting .NET Framework 2.0 or later. To achieve this, proceed as follows:

The .NET assemblies (*.NET.dll) are added as references to the project; they are needed at compile time. PDFParser.dll is not a .NET assembly, but a native library. It is not added as a reference to the project. Instead, it is loaded during execution of the application.

For the operating system to find and successfully load the native library PDFParser.dll, it must match the executing application's bitness (32-bit versus 64-bit) and it must reside in either of the following directories:

- In the same directory as the application that uses the library
- In a subdirectory win-x86 or win-x64 for 32-bit or 64-bit applications, respectively
- In a directory that is listed in the PATH environment variable

In Visual Studio, when using the platforms "x86" or "x64", you can do this by adding the 32-bit or 64-bit PDFParser.dll, respectively, as an "existing item" to the project, and setting its property "Copy to output directory" to true. When using the "AnyCPU" platform, make sure, by some other means, that both the 32-bit and the 64-bit PDFParser.dll are copied to subdirectories win-x86 and win-x64 of the output directory, respectively.

2.5.4 C interface

- The header file `expa_c.h` needs to be included in the C/C++ program.
- On Windows operating systems, the library `PDFParser.lib` needs to be linked to the project.
- The dynamic link library `PDFParser.dll` needs to be in a path of executables (e.g. on the environment variable `%PATH%`).

2.6 Uninstall, Install a new version

If you have used the ZIP file for the installation, undo all the steps done during installation, e.g. de-register using `regsvr32.exe /u`, delete all files, etc.

Installing a new version does not require you to previously uninstall the old version. The files of the old version can directly be overwritten with the new version.

2.7 Color profiles

When extracting images, a color conversion may be necessary.

For calibrated color spaces (such color spaces with an associated ICC color profile), the color conversion is well defined. For the conversion of uncalibrated device color spaces (DeviceGray, DeviceRGB, DeviceCMYK), however, the 3-Heights® PDF Extract API requires appropriate color profiles. Therefore, it is important that the profiles are available and that they describe the colors of the device your input documents are intended for.

If no color profiles are available, default profiles for both RGB and CMYK are generated on the fly by the 3-Heights® PDF Extract API.

2.7.1 Default color profiles

If no particular color profiles are set, default profiles are used. For device RGB colors, a color profile named "sRGB Color Space Profile.icm" and for device CMYK, a profile named "USWebCoatedSWOP.icc" are searched for in the following directories:

Windows

1. %SystemRoot%\System32\spool\drivers\color
2. directory Icc, which must be a direct subdirectory of where the PDFParser.dll resides.

Linux and macOS

1. \$PDF_ICC_PATH if the environment variable is defined
2. the current working directory

2.7.2 Get other color profiles

Most systems have pre-installed color profiles available. For example, on Windows at %SystemRoot%\system32\spool\drivers\color\. Color profiles can also be downloaded from the links provided in the directory bin\Icc\ or from the following websites:

- <https://www.pdf-tools.com/public/downloads/resources/colorprofiles.zip>
- <https://www.color.org/srgbprofiles.html>

3 License management

The 3-Heights® PDF Extract API requires a valid license in order to run correctly. If no license key is set or the license is not valid, then most of the interface elements documented in [Interface reference](#) fail with an error code and error message indicating the reason.

More information about license management is available in the [license key technote](#).

4 Programming interfaces

4.1 Visual Basic 6

After installing the 3-Heights® PDF Extract API and registering the COM interface (see [Installation and deployment](#)), you find a Visual Basic 6 example with file extension .vpb in the directory `samples/VB/`. You can either use this sample as a base for an application, or you can start from scratch.

If you start from scratch, perform these steps:

1. Create a new Standard-Exe Visual Basic 6 project. Then include the 3-Heights® PDF Extract API component to your project.

2. Draw a new Command Button and optionally, rename it as appropriate.
3. Double-click the command button and insert the few lines of code below. All that you need to change is the path of the file name.

```
Private Sub Command1_Click()  
    Dim doc As New PDFPARSERLib.Document  
  
    If Not doc.Open("C:\path\input.pdf", "") Then  
        MsgBox "Could not open PDF file. Error: " & doc.LastError  
        Exit Sub  
    End If  
  
    MsgBox "Number of pages in the PDF: " & doc.PageCount  
  
    doc.Close  
End Sub
```

4.2 ASP script

The PDF Extract component can be accessed in an ASP script using the call `Server.CreateObject` and a class name as parameter.

For example, to create PDF Extract Document object, use a command like this:

```
set pdfDoc = Server.CreateObject("PDFParser.Document")
```

Here is a small ASP sample how to create a document object and then retrieve the total number of pages in a PDF file. The path to the PDF `myfile.pdf` needs to be modified.

Example:

```
<%@ Language=VBScript %>
<%
    option explicit
    dim pdfDoc
    set pdfDoc = Server.CreateObject("PDFParser.Document")
    if not pdfDoc.Open(Server.MapPath("myfile.pdf")) then
        Response.Write "<p>"
        Response.Write "Could not open file." & "<br>"
    end if
    Response.Write "<p>"
    Response.Write "Number of pages: " & pdfDoc.PageCount & "<br>"
    Response.Write "</p>"
%>
```

4.3 .NET

There should be at least one .NET sample for MS Visual Studio available in the ZIP archive of the Windows version of the 3-Heights® PDF Extract API. The easiest to quickly start is to refer to this sample.

To create a new project from scratch, perform the following steps:

1. Start Visual Studio and create a new C# or VB project.
2. Add references to the NuGet package `PdfTools.PDFParser 6.27.2`, as described in [NuGet package](#).
3. Import namespaces (Note: This step is optional, but useful.)
4. Write your code.

Steps 3 and 4 are shown separately for C# and Visual Basic.

4.3.1 Visual Basic

3. Double-click "My Project" to view its properties. On the left hand side, select the menu "References". The .NET assemblies you added before should show up in the upper window. In the lower window, import the namespaces `PdfTools.Pdf`, `PdfTools.PdfRenderer`, and `PdfTools.PdfExtractNET`.

You should now have settings similar as in the screenshot below:

- The .NET interface can now be used as shown below:

Example:

```
Dim document As New Pdftools.PdfExtract.Document()
document.Open(...)
document.PageNo = 1
Dim content = document.Page.Content
...
```

4.3.2 C#

- Add the following namespaces:

Example:

```
using Pdftools.Pdf;
using Pdftools.PdfRenderer;
using Pdftools.PdfExtractNET;
```

4. The .NET interface can now be used as shown below:

Example:

```
using (Document document = new Document())
{
    document.Open(...);
    document.PageNo = 1;
    Content content = document.Page.Content;
    ...
}
```

4.3.3 Deployment

This is a guideline on how to distribute a .NET project that uses the 3-Heights® PDF Extract API:

1. The project must be compiled using Microsoft Visual Studio. See also [.NET interface](#).
2. For deployment, all items in the project's output directory (e.g. `bin\Release`) must be copied to the target computer. This includes the 3-Heights® PDF Extract API's .NET assemblies (`*.NET.dll`), as well as the native library (`PDFParser.dll`) in its 32 bit or 64 bit version or both. The native library can alternatively be copied to a directory listed in the PATH environment variable, e.g. `%SystemRoot%\System32`.
3. It is crucial that the native library `PDFParser.dll` is found at execution time, and that the native library's format (32 bit versus 64 bit) matches the operating system.
4. The output directory may contain multiple versions of the native library, e.g. for Windows 32 bit, Windows 64 bit, MacOS 64 bit, and Linux 64 bit. Only the versions that match the target computer's operating system need be deployed.
5. If required by the application, optional DLLs must be copied to the same folder. See [Deployment](#) for a list and description of optional DLLs.

4.3.4 Troubleshooting: `TypeInitializationException`

The most common issue when using the .NET interface is that the correct native DLL `PDFParser.dll` is not found at execution time. This normally manifests when the constructor is called for the first time and an exception of type `System.TypeInitializationException` is thrown.

This exception can have two possible causes, which you distinguish by the inner exception (property `InnerException`):

`System.DllNotFoundException` Unable to load DLL `PDFParser.dll`: The specified module could not be found.

`System.BadImageFormatException` An attempt was made to load a program with an incorrect format.

The following sections describe in more detail how to resolve these issues.

Troubleshooting: `DllNotFoundException`

This means that the native DLL `PDFParser.dll` could not be found at execution time.

Resolve this by performing one of these actions:

- Use the [NuGet package](#).
- Add `PDFParser.dll` as an existing item to your project and set its property "Copy to output directory" to "Copy if newer", or

- Add the directory where `PDFParser.dll` resides to the environment variable `%Path%`, or
- Manually copy `PDFParser.dll` to the output directory of your project.

Troubleshooting: BadImageFormatException

The exception means that the native DLL `PDFParser.dll` has the incorrect “bitness” (i.e. platform 32 vs. 64 bit). There are two versions of `PDFParser.dll` available in the [ZIP archive](#): one is 32-bit (directory `bin\Win32`) and the other 64-bit (directory `bin\x64`). It is crucial that the platform of the native DLL matches the platform of the application’s process.

(Using the [NuGet package](#) normally ensures that the matching native DLL is loaded at execution time.)

The platform of the application’s process is defined by the project’s platform configuration for which there are three possibilities:

AnyCPU This means that the application runs as a 32-bit process on 32-bit Windows and as 64-bit process on 64-bit Windows. When using AnyCPU, then the correct native DLL must be used, depending on the Windows platform. You can perform this either when installing the application by installing the matching native DLL, or at application start-up by determining the application’s platform and ensuring the matching native DLL is loaded. The latter can be achieved by placing both the 32 bit and the 64 bit native DLL in subdirectories `win-x86` and `win-x64` of the application’s directory, respectively.

x86 This means that the application always runs as 32-bit process, regardless of the platform of the Windows installation. The 32-bit DLL runs on all systems.

x64 This means that the application always runs as 64-bit process. As a consequence, the application will not run on a 32-bit Windows system.

5 User guide

There are various code samples in the product download kit of the 3-Heights® PDF Extract API.

5.1 Text extraction

For text extraction, a page number must be set using the [PageNo](#) property. Then, the [GetNextText](#) method returns the text tokens in z order. This means the text token that is on top (i.e. is rendered last when the document is displayed) is retrieved last. Some PDF creators save the text in the order from the upper left to the lower right corner. As a result, extracting such documents, yields in a readable text sequence. However, this is not true for all creators. It is as well possible to save every single character separately and in random order. Extracting text from such a document results in a random and therefore, unreadable sequence of text tokens. The text tokens first need to be sorted by coordinate to make the text readable.

5.1.1 Undesired or missing blanks

Using the [TextExtConfiguration](#) property, the text extraction algorithm can be configured. It is best to start with one of the settings recommended for your use case.

Sometimes, a configuration can lead to undesired blanks within what visually looks as one word.

For example if:

- Text is written with different subsets of the same font. Different subsets of a font are considered different fonts. Therefore, if the font changes within what visually looks as one word, it is separated.
- Text is not written on the same horizontal line. This can occur in some documents whose text stems from OCR (optical character recognition). There is a built-in tolerance to take account of this. However, if vertical offsets are too large, a new word starts.
- Various possible errors in the font such as incorrect or missing width values of the glyphs (in particular of the blank), incorrect encoding, etc.

In all of the above cases, the coordinates need to be considered. Instead of inserting blanks after each word (as in the sample), the coordinate and width of the previous text token needs to be compared with the position of the next text token.

If text is concatenated, i.e. blanks are missing, decrease the property [SpaceFactor](#), for example, to the value **0.2**.

5.1.2 Extracted text is unreadable

Fonts contain a particular set of glyphs. A glyph is a specific graphical rendering of a character. The glyphs *P*, **P** and *P* are glyphs of the character “P”.

Fonts have an encoding, such as WinAnsi, MacRoman, or custom encoding. The encoding maps the glyphs to a character. If the encoding in a font is missing, it is assumed it is WinAnsi encoded.

When an encoding is missing or incorrect, the text is not extractable. Even if the text is visually readable, if the meaning of the glyphs is not encoded, it cannot be extracted (except by means of OCR).

If text is not extractable using text selection in the Adobe Reader, then it probably cannot be extracted with the 3-Heights® PDF Extract API and vice versa.

5.1.3 Handling symbolic and non-symbolic fonts

Fonts in PDF documents have font descriptor flags (see [PDF Reference 1.7](#), section 5.7.1). These flags describe the font characteristics such as fixed pitch, serif, symbolic, italic, etc. If a font is flagged symbolic, it means its glyphs are not part of the standard Latin character set. Typical symbolic glyphs are squares, stars, or other small icons such as cars or animals. Often there is no Unicode for these glyphs. The 3-Heights® PDF Extract API handles text extraction of symbolic and non-symbolic fonts as described below.

If there is no encoding provided with the font, the intrinsic encoding is applied, which works as follows:

- If the font file is embedded:
 - If there is a Unicode for the glyph, the corresponding Unicode is returned.
 - If there is no Unicode and the font is flagged symbolic, and it meets the condition:
 - part of the glyph names consist of a numerical value, such as G1, G2,...G100, the corresponding glyph number (and for TrueType fonts the Unicode Private Section prefix 0xF000) is returned. Otherwise, the glyph index is returned.
 - the font is non-symbolic, the standard encoding is used.
- If the font file is not embedded: The standard encoding is applied.

Notes about the algorithm:

- When the standard encoding is applied, all control characters (<31) are mapped to character 32 (blank).
- The glyph numbers G1, G2... G100 are often created by GhostScript-related PDF creators. In these cases, the number in the glyph name corresponds to the encoding of the used code page. For example, G65 is the character A in WinAnsi encoding.

5.1.4 Text extraction of text marked as symbolic

Sometimes text is marked as symbolic, but it actually is not. In certain cases, PDF creators do this to prevent text extraction. Assuming a PDF contains a TrueType font that is by mistake marked as symbolic. As a result, the returned characters contain the Unicode Private Use Area prefix 0xF000 to 0xFFFF. In this case, the prefix needs to be removed again. This can be achieved by setting the [TranslateSymbolic](#) property to **True**.

Note: Since only the Unicode Private Use Area is affected by this translation, it is generally recommended to set this option to **True**.

5.2 Image extraction

An image is placed on the output page in any position, orientation, and size as specified by the current transformation matrix ([CTM](#) property of the current graphics state). The image space that is transformed by the CTM is the unit square [0 0 1 1], i.e. the unit square is mapped to the rectangle or parallelogram in which the image is to be painted. For example, the coordinate on the page of the bottom right corner of the untransformed image is the transformation of the coordinate (1 1).

5.2.1 Image resolution

Images are resources in a PDF document. Every image can be referenced multiple times in the document. The image itself doesn't have resolution. It only has a resolution when referenced on a page. The resolution depends on the ratio of the dimensions of the image and its size on the page. It can be different every time.

5.2.2 Image orientation

Images can be stored with an orientation other than TopLeft (default). To display them visually correctly, there is a transformation matrix applied to invert the orientation. To ensure the images are saved with the same orientation as they are displayed on the PDF, use the [ChangeOrientation](#) method as shown in the sample.

5.3 Optional content (Layers)

To associate content objects to Optional Content Groups (OCGs) that define their visibility, the following steps have to be taken:

- 1. [IgnoreOCM](#) property must be set to true.
- 2. Use the [Content](#) interface's [getNextObject](#) method to extract content objects.
- 3. Whenever a BeginOCM operator is encountered, the [OCM](#) property contains the optional content membership string that defines the visibility of subsequent content objects, until the matching EndOCM operator is encountered.
- 4. The respective OCG can be retrieved using the document's [GetOcg](#), [OcgCount](#) method.

As an example, look at the document www.pdf-tools.com/public/downloads/samples/layers.pdf. It contains six colored squares and six OCGs. The visibility of the red, green, and blue squares is controlled by the relevant OCGs. The yellow square is only visible, if both OCGs "Green" and "Blue" are ON. The OCGs "Gray 64" and "Gray 128" are child elements of the OCG "Gray" and control the visibility of the respective gray OCGs. These are visible only, if both the child and the parent OCG are ON.

Extracting OCGs from `layers.pdf`:

ID	name	level
0	Red	0
1	Green	0
2	Blue	0
3	Gray	0
4	Gray 64	1
5	Gray 128	1

Extracting objects from `layers.pdf`:

Type	Property = Value	Comment
BeginOCM	OCM="0"	Visibility of subsequent objects is defined by the state of OCG 0 ("Red")
..Path	Path=red square	
EndOCM		End of OCM segment
BeginOCM	OCM="1"	OCG 1 is "Green"

..Path	Path=green square	
EndOCM		
BeginOCM	OCM="2"	OCG 2 is "Blue"
..Path	Path=blue square	
EndOCM		
BeginOCM	OCM="1 && 2"	Subsequent objects are visible, if OCG 1 and OCG 2 are ON.
..Path	Path=yellow square	
EndOCM		
BeginOCM	OCM="3"	OCG 3 is "Gray", parent OCG of 4 and 5
..BeginOCM	OCM="4"	Note that OCM blocks can be nested, typically uses for hierarchical OCGs
....Path	Path=gray 64 square	
..EndOCM		
..BeginOCM	OCM="5"	OCG 5 is "Gray 128"
....Path	Path=gray 128 square	
..EndOCM		
EndOCM		

6 Interface reference

This manual describes the COM interface only. Other interfaces (C, Java, .NET) work similarly, i.e. they have calls with similar names and the call sequence to be used is the same as with COM.

6.1 Document Interface

6.1.1 Author

Property (get): String Author

Get the author entry from the document's info object. See [GetInfoEntry](#) for retrieving arbitrary entries from the info object.

6.1.2 Close

Method: Void Close()

Close the currently opened document. If the document is already closed, the method does nothing.

6.1.3 Compliance

Property (get): TPDFCompliance Compliance

Get the claimed conformance of the document. For instance, this property can be used in order to detect if the document claims to be PDF/A.

6.1.4 CreationDate

Property (get): Date CreationDate

Get the creation date of the document's info object. See [GetInfoEntry](#) for retrieving arbitrary entries from the info object.

6.1.5 Creator

Property (get): String Creator

Get the name of the creator from the document's info object. See [GetInfoEntry](#) for retrieving arbitrary entries from the info object.

6.1.6 GetDestination

Method: `Destination GetDestination(String Destination)`

Retrieve an interface to the destination specified in the parameter.

Returns:

- A [Destination](#) object if the specified destination exists.
- **Nothing** otherwise.

Parameter:

Destination [`String`] The named destination

6.1.7 DPartRoot

Property (get): `DPartRoot DPartRoot`

Get a [DPartRoot](#) object that represents the document parts' root element of a PDF 2.0 or a PDF/VT document. If no document part information is present, then this property returns **Nothing**.

6.1.8 GetFirstColorSpaceResource, GetNextColorSpaceResource

Method: `ColorSpace GetFirstColorSpaceResource()`

Method: `ColorSpace GetNextColorSpaceResource()`

Use [GetFirstColorSpaceResource](#) to get the first color space resource. After this, you can use [GetNextColorSpaceResource](#) to get further color space resources.

Returns:

- A [ColorSpace](#) object for the next color space resource, if there is any.
- **Nothing** otherwise.

6.1.9 GetFirstEmbeddedFile, GetNextEmbeddedFile

Method: `EmbeddedFile GetFirstEmbeddedFile()`

Method: `EmbeddedFile GetNextEmbeddedFile()`

Use [GetFirstEmbeddedFile](#) to get the first embedded file. After this, you can use [GetNextEmbeddedFile](#) to get further embedded files. Embedded files of both the document's collection (PDF portfolio) and of FileAttachment annotations are returned.

Returns:

- An [EmbeddedFile](#) object for the next embedded file, if there is any.
- **Nothing** otherwise.

6.1.10 GetFirstFontResource, GetNextFontResource

Method: `Font GetFirstFontResource()`

Method: `Font GetNextFontResource()`

Use [GetFirstFontResource](#) to get the first font resource. After this, you can use [GetNextFontResource](#) to get further font resources.

Returns:

- A [Font](#) object for the next font resource, if there is any.
- **Nothing** otherwise.

6.1.11 GetFirstImageResource, GetNextImageResource

Method: `Image GetFirstImageResource()`

Method: `Image GetNextImageResource()`

Use [GetFirstImageResource](#) to get the first image resource. After this, you can use [GetNextImageResource](#) to get further image resources.

6.1.12 GetFirstOutlineItem, GetNextOutlineItem

Method: `OutlineItem GetFirstOutlineItem()`

Method: `OutlineItem GetNextOutlineItem(Long MaxLevel, Boolean ReturnOpenOnly)`

Method: `Long GetCurrentOutlineLevel()`

Use [GetFirstOutlineItem](#) to get the first outline item (bookmark). After this, you can use [GetNextOutlineItem](#) to get further outline items. After having called [GetFirstOutlineItem](#) or [GetNextOutlineItem](#), you can call [GetCurrentOutlineLevel](#) to get the level of the outline item in the hierarchy of outlines. A level of 0 corresponds to the root level.

Parameters:

MaxLevel [`Long`] (optional, default **20**) The maximum level of the depth of the outlines.

ReturnOpenOnly [`Boolean`] (optional, default **False**) Return only outlines which are opened.

Returns:

- An [OutlineItem](#) object for the next outline item, if there is any.
- **Nothing** otherwise.

6.1.13 GetInfoEntry

Method: `String GetInfoEntry(String szKey)`

Return the value of an entry in the document info dictionary. Popular entries specified in the [PDF Reference 1.7](#) are **"Title"**, **"Author"**, **"Subject"**, **"Creator"** (sometimes referred to as Application), and **"Producer"** (sometimes referred to as PDF Creator). See [PDF Reference 1.7](#) section "10.2.1 Document Information Dictionary" for more information about the document's info dictionary.

Parameter:

szKey [`String`] The string, such as **"Author"** or **"Subject"**, defining the entry in the document info dictionary.

Returns:

- The string corresponding to the entry, if it exists.
- **Nothing** otherwise.

6.1.14 GetPDFObject

Method: `PDFObject GetPDFObject(String Path)`

Get a PDF object from a path string.

Parameter:

Path [`String`] The path consists of a prefix and operators. (In the following example, the symbols `<` and `>` are used to mark a placeholder.)

Prefix:

- **"\$/"**: Trailer dictionary (see section 3.4.4 of the [PDF Reference 1.7](#)), valid entries are **"\$/Root"**, **"\$/Info"**, and **"\$/Encrypt"**.
- **"%<n>/"**: Page `<n>`

Path Operators:

- **"/<name>"**: Entry `<name>` of the dictionary
- **"[<i>]"**: Index `<i>` in the array

Examples:

- **"\$/Root/Pages/Kids[0]/Contents"**

- "%1/Resources/Font/TT2/FontDescriptor/FontFamily"

Returns:

A [PDFObject](#) interface to the PDF object specified by the [Path](#) string.

6.1.15 GetOcg, OcgCount

Property (get): Long [OcgCount](#)
Method: [Ocg](#) [GetOcg](#)(Long [Count](#))

Use [OcgCount](#) to get the number of optional content groups (OCGs), also known as “layers”, of the document. An actual OCG can be retrieved with [GetOcg](#).

Parameter:

[Count](#) [Long] The number of the optional content group. Optional content groups are numbered from 0 to [OcgCount](#)-1.

Returns:

A [Ocg](#) object for the requested OCG.

6.1.16 GetPageLabel

Method: String [GetPageLabel](#)(Long [PageNo](#))

Get the label text associated with a specific page given its number. Examples for page labels are: "7", or "vii".

Parameter:

[PageNo](#) [Long] The page number

Returns:

A string holding the page label if a page label exists. If no page label exists, the page number is converted to a string and returned.

6.1.17 GetXMPMetadata

Method: Boolean [GetXMPMetadata](#)(String [FileName](#))

Extract the document's XMP metadata stream and write it to the specified file.

Parameter:

FileName [String] The name of the output file

Returns:

True if the document contains XMP metadata and the stream was successfully written to the output file.

False otherwise.

6.1.18 GetXMPMetadataMem

Method: Variant `GetXMPMetadataMem()`

Extract the document's XMP metadata stream as a byte array. If the document does not contain XMP metadata, **Nothing** is returned.

6.1.19 IsCollection

Property (get): Boolean `IsCollection`

This property is **True** if the PDF document is a collection (aka PDF Portfolio) and **False** otherwise.

6.1.20 IsEncrypted

Property (get): Boolean `IsEncrypted`

This property is **True** if the PDF document has an encryption entry and **False** otherwise.

6.1.21 IsLinearized

Property (get): Boolean `IsLinearized`

This property is **True** if the linearization flag is set in the PDF document and **False** otherwise. This property does not actually validate whether the linearization is correct.

Linearization refers to optimizing the PDF for fast web access, i.e. support random page access.

6.1.22 Keywords

Property (get): String `Keywords`

Get a string with the keywords of the document's info object.

6.1.23 LastError

Property (get): `TPDFErrorCode` `LastError`

This property can be accessed to receive the latest error code. Any return value other than `PDF_S_SUCCESS` (0) indicates that an error occurred. See [TPDFErrorCode](#).

6.1.24 LastErrorMessage

Property (get): String `LastErrorMessage`

Get the error message text associated with the last error (see also [LastError](#)).

The property is `Nothing` if no message is available.

6.1.25 LicenseIsValid

Property (get): Boolean `LicenseIsValid`

This property is `True` if a valid license key has been set or configured and `False` otherwise.

6.1.26 MajorVersion, MinorVersion

Property (get): Short `MajorVersion`

Property (get): Short `MinorVersion`

Get the major and minor version of the document. For example, PDF Version 1.5 (which corresponds to Adobe Acrobat 6) yields `MajorVersion=1` and `MinorVersion=5`.

6.1.27 ModDate

Property (get): Date `ModDate`

Get the modification date of the info object of the document.

6.1.28 Open

Method: Boolean `Open(String Filename, String Password)`

Open a PDF file, i.e. make the objects contained in the document accessible. If another document is already open, it is closed first.

Parameters:

Filename [`String`] The file name and optionally, the file path, drive or server string according to the operating systems file name specification rules.

Password [`String`] (optional) The user or the owner password of the encrypted PDF document. If this parameter is left out, an empty string is used as a default.

Returns:

True The file could be successfully opened.

False The file does not exist, it is corrupt, or the password is not valid. Use the [LastError](#) property for additional information.

6.1.29 OpenMem

Method: Boolean `OpenMem(Variant MemBlock, String Password)`

Open a PDF file, i.e. make the objects contained in the document accessible. If a document is already open, it is closed first.

Parameters:

MemBlock [`Variant`] The memory block containing the PDF file given as a one-dimensional byte array.

Password [`String`] (optional) The user or the owner password of the encrypted PDF document. If this parameter is left out, an empty string is used as a default.

Returns:

True The document could be successfully opened.

False The document could not be opened, it is corrupt, or the password is not valid.

6.1.30 OpenStream

Method: Boolean `OpenStream(Variant Stream, String Password)`

Open a PDF file, i.e. make the objects contained in the document accessible. If a document is already open, it is closed first.

Parameters:

Stream [Variant] The stream providing the PDF file. The stream must support random access.

Password [String] (optional) The user or the owner password of the encrypted PDF document. If this parameter is left out, an empty string is used as a default.

Returns:

True The document could be successfully opened.

False The document could not be opened, it is corrupt, or the password is not valid.

6.1.31 Page

Property (get): Page Page

This property retrieves a [Page](#) interface to the currently selected page of a document.

Note: Before querying this property, make sure that [PageNo](#) is set.

6.1.32 PageCount

Property (get): Long PageCount

Get the number of pages of an open document. If the document is closed or if the document is a collection (also known as PDF portfolio), then this property is 0.

6.1.33 PageNo

Property (get, set): Long PageNo

Set or get the currently selected page of an open document given its page number. If the document is closed, this property evaluates to 0.

The numbers are counted starting from 1 for the first page to the value of [PageCount](#) for the last page.

6.1.34 Producer

Property (get): String `Producer`

Get the name of the producer from the document's info object.

6.1.35 ProductVersion

Property (get): String `ProductVersion`

Get the version of the 3-Heights® PDF Extract API in the format "A.C.D.E".

6.1.36 SetLicenseKey

Method: Boolean `SetLicenseKey(String LicenseKey)`

Sets the license key.

6.1.37 Subject

Property (get): String `Subject`

Get the subject from the document's info object.

6.1.38 Title

Property (get): String `Title`

Get the title from the document's info object.

6.2 Page Interface

6.2.1 ArtBox

Property (get): Variant `ArtBox`

Use this property to get the PDF "ArtBox" rectangle, given by the coordinates left, bottom, right, top. The values are returned as an array of four single precision real numbers. The ArtBox is optional. It defines the region that contains meaningful content intended by the creator. If there is no ArtBox set, the CropBox is returned.

6.2.2 BleedBox

Property (get): Variant [BleedBox](#)

Use this property to get the PDF “BleedBox” rectangle, given by the coordinates left, bottom, right, top. The values are returned as an array of four single precision real numbers. The BleedBox is optional. It defines the region to which the contents of the page should be clipped when output in a production environment. If there is no BleedBox set, the CropBox is returned.

6.2.3 Content

Property (get): Content [Content](#)

Access the [Content](#) object for the content stream of the page.

6.2.4 CropBox

Property (get): Variant [CropBox](#)

Use this property to get the PDF “CropBox” rectangle, given by the coordinates left, bottom, right, top. The values are returned as an array of four single precision real numbers. The CropBox is optional. It defines the range of the visible region of the page. If there is no CropBox set, the MediaBox is returned.

6.2.5 DeviceColorant

Property (get): String [DeviceColorant](#)

Get the device colorant.

6.2.6 Document

Property (get): Document [Document](#)

Get the [Document](#) object this page belongs to.

6.2.7 GetFirstAnnotations, GetNextAnnotation

Method: Annotation [GetFirstAnnotation\(\)](#)

Method: Annotation [GetNextAnnotation\(\)](#)

Use [GetFirstAnnotation](#) to get the first annotation. After this, you can use [GetNextAnnotation](#) to get further annotations. Return an interface to the next annotation.

Returns:

- An [Annotation](#) object for the next annotation, if there is any.
- **Nothing** otherwise.

6.2.8 HasColor

Property (get, set): Boolean [HasColor](#)

This property is **True** if the page contains color and **False** otherwise.

6.2.9 MediaBox

Property (get): Variant [MediaBox](#)

Use this property to get the PDF "MediaBox" given by the coordinates left, bottom, right, top. The values are returned as an array of four single precision real numbers. The media box is required. It defines the physical boundaries of the medium on which the page is intended to be displayed or printed.

Usually the MediaBox is rotated by viewer applications according to the [Rotate](#) property.

6.2.10 Rotate

Property (get): Integer [Rotate](#)

Return the rotation value of the page. This value is used by viewer programs to turn the page by the given number of degrees while displaying. A positive number turns the page clockwise. The value must be a multiple of 90, i.e. valid values are **-270, -180, -90, 0, 90, 180, 270**.

6.2.11 TrimBox

Property (get): Variant [TrimBox](#)

Use this property to get the PDF "TrimBox" rectangle, given by the coordinates left, bottom, right, top. The values are returned as an array of four single precision real numbers. The TrimBox is optional. It defines the intended dimensions of the finished page after trimming. If there is no TrimBox set, the CropBox is returned.

6.3 Content Interface

The Content object provides information about the content of a PDF page. To obtain a Content object, use the [Content](#) method of the Page interface.

6.3.1 BreakWords

[Deprecated] Property (get, set): Boolean [BreakWords](#)

This property is deprecated. The former behavior of [BreakWords](#) can be simulated by setting the following flags in the [TextExtConfiguration](#) property:

- [BreakWords](#) = **True**: Set the [eTECBreakSpaceUnicode](#) flag and clear the [eTECPosMergeSingleSpace](#) and [eTECPosMergeMultiSpace](#) flags.
- [BreakWords](#) = **False**: Clear the [eTECBreakSpaceUnicode](#) flag and set the [eTECPosMergeSingleSpace](#) and [eTECPosMergeMultiSpace](#) flags.

6.3.2 BoundingBox

Property (get, set): Variant [BoundingBox](#)
Default: [CropBox](#) of the page

The bounding box is a rectangle in user space units (1/72 inch). The rectangle is used, when the [Reset](#) method is called with [AccountForRotate](#) set to **True** and has an effect on the coordinate transform. The bounding box must be set before calling [Reset](#).

6.3.3 ConvertPathToImage

Property (get, set): Boolean [ConvertPathToImage](#)
Default: **False**

This property works in conjunction with the [GetNextObject](#) method. When [ConvertPathToImage](#) is set to **True**, paths are converted and rendered, and [GetNextObject](#) then returns images instead of paths.

True Convert paths into images with an alpha channel.

False Paths are returned natively.

Note: Images contain a transparent background if the image format supports an alpha channel, such as TIF or PNG.

See also [PathImageAntiAlias](#), [PathImageBGColor](#), and [PathImageResolution](#).

This property was first introduced in version 1.9.19.1. In version 4.6.26.0, it was re-implemented using the R2 rendering engine.

6.3.4 ExpandLigatures

Property (get, set): Boolean `ExpandLigatures`
Default: `False`

When `ExpandLigatures` is set to `True`, ligatures such as `fi`, `ff`, `fl`, etc. found during text extraction are converted to individual characters `fi`, `ff`, `fl`, etc.

6.3.5 Flags

Property (get, set): Long `Flags`

If annotations are being extracted, then this property accesses the annotation flags (see also `Flags` property in the `Annotation` interface). Otherwise, this property is `-1`.

6.3.6 GetNextImage

Method: Image `GetNextImage()`

This method reads the content stream objects until an image object can be returned or the end of the content stream is reached. If an image object was found, an `Image` object is returned. Alternatively, the same interface can be retrieved through the `Image` property. The corresponding graphics state can be retrieved through the `GraphicsState` property.

Returns:

- An `Image` object for the next image on the current page, if there is any.
- `Nothing` otherwise.

6.3.7 GetNextObject

Method: TPDFContentObject `GetNextObject()`

This method reads the content stream objects until a text, image, or path object is found or the end of the content stream is reached.

Returns:

- eNone** The end of the content stream has been reached.
- eText** A text object was found and its interface can be retrieved through the `Text` property.
- eImage** An image object was found and its interface can be retrieved through the `Image` property. The corresponding graphics state can be retrieved through the `GraphicsState` property.

ePath A path object was found and its string representation can be retrieved through the [Path](#) property. The corresponding graphics state can be retrieved through the [GraphicsState](#) property.

eSave Save the current graphics state on the graphics state stack.

eRestore Restore the graphics state by removing the most recently saved state from the stack and making it the current graphics state.

eBeginOCM Marks the start of a sequence of objects, whose visibility is defined by optional content membership (OCM). The string representation of the OCM can be retrieved through the [OCM](#) property. OCM sequences can be nested.

eEndOCM Marks the end of an OCM sequence.

6.3.8 GetNextPath

Method: `String GetNextPath()`

This method reads the content stream objects until a path object is found or the end of the content stream is reached. If a path object is found, a string representation of a path object is returned. Alternatively, the same string can be retrieved through the [Path](#) property. The corresponding graphics state can be retrieved through the [GraphicsState](#) property.

Returns:

- A string representation of the next text path on this page, if there is any.
- **Nothing** otherwise.

6.3.9 GetNextText

Method: `Text GetNextText()`

This method reads the content stream objects until a text object is found or the end of the content stream is reached. If a text object is found, a [Text](#) object is returned. The corresponding graphic state can be retrieved through the [GraphicsState](#) property.

In contrast to the [GetNextImage](#) and [GetNextPath](#) methods, this method may read several text objects and merge them until a major text property (font, line coordinate, etc.) changes or a word break occurs if word breaking is enabled. This merging behavior is configured with the [TextExtConfiguration](#) and [SpaceFactor](#) properties.

Returns:

- A [Text](#) object for the next text, if there is any on this page.
- **Nothing** otherwise.

6.3.10 GraphicsState

Property (get): GraphicsState GraphicsState

Get the current [GraphicsState](#) object.

The graphics state is updated if any of the following methods is called:

- [GetNextText](#)
- [GetNextImage](#)
- [GetNextPath](#)
- [GetNextObject](#)

6.3.11 IgnoreOCM

Property (get, set): Boolean IgnoreOCM

Set this property to **True** to ignore optional content membership and make all content visible. BeginOCM and EndOCM objects are extracted, but they have no effect on the extracted content. For example, when set to **True**, hidden text is extracted as well. Set this property to **True** to extract all content.

6.3.12 Image

Property (get): Image Image

Get a the last read [Image](#) object. The image object is updated each time the [GetNextImage](#) method is called or when [GetNextObject](#) returns [eImage](#). The corresponding graphics state can be retrieved through the [GraphicsState](#) property.

6.3.13 OCM

Property (get): String OCM

Get the current optional content membership (OCM) string, which defines the visibility as a Boolean function of OCG IDs in C syntax. Retrieve the respective OCG using the [GetOcg, OcgCount](#) method of the [Document](#) interface. Supported operators are "&&", "|", and "!".

Example: "**1** && **2**" means that the following objects are visible only if OCG 1 and OCG 2 are visible.

Note: This property is valid only immediately after [GetNextObject](#) returned [eBeginOCM](#).

6.3.14 Path

Property (get): String Path

Get a string representation of the last read path object. The path object is updated each time the [GetNextPath](#) method is called or when [GetNextObject](#) returns [ePath](#). The corresponding graphics state can be retrieved through the [GraphicsState](#) property.

A path object describes a graphic drawing consisting of stroked lines and curves as well as filled shapes. The string contains the PDF path construction tokens consisting of real value operands (in angle brackets) followed by operator mnemonics:

- Move current point to: <x> <y> m
- Line from current point to: <x> <y> l
- Rectangle: <x> <y> <w> <h> re
- Cubic Bezier curve from current point to: <x1> <y1> <x2> <y2> <x3> <y3> c
- Close figure (move to start of last sub-path): h
- Fill path: f
- Stroke path: s
- End path (without filling and stroking): n
- Modify current clipping path: W

The exact details to the path construction operators can be found in the [PDF Reference 1.7](#).

Note: Calling the method [Reset](#) prior to extracting paths has an influence on the values of the coordinates of the path construction operators.

6.3.15 PathImageAntiAlias

Property (get, set): Boolean PathImageAntiAlias

Enables or disables anti-aliasing for the generated image when using [ConvertPathToImage](#).

6.3.16 PathImageBGColor

Property (get, set): Long PathImageBGColor
Default: 0xFFFFFFFF

Set or get the background color as RGB value of the generated image when using [ConvertPathToImage](#). The format is 0x<BB><GG><RR>, where <BB>, <GG>, and <RR> are hexadecimal numbers in the range 00-FF that represent the values of the blue, green, and red channel, respectively. The default 0xFFFFFFFF is white.

Note: The image background is always transparent, or white for image formats such as JPEG that do not support transparency. The anti-aliasing is computed with the color specified in this property as a backdrop. Hence, this property only has an effect if [PathImageAntiAlias](#) is [True](#).

6.3.17 PathImageResolution

Property (get, set): `Single PathImageResolution`
Default: `150`

Set or get the resolution in DPI of the generated image when using [ConvertPathToImage](#).

6.3.18 Reset

Method: `Void Reset(Boolean AccountForRotate)`

This method resets the content extraction process, i.e. it sets the point of extraction to the beginning of the content stream.

Parameter:

AccountForRotate [`Boolean`] (Optional, default=`False`) This parameter allows you to configure two modes for offsetting the coordinate system origin. This affects the coordinates of extracted content elements.

False The coordinates are extracted as raw coordinates as used in the PDF document.

True Extracted coordinates are relative to the bottom left corner of the visible page as displayed by a viewer. I.e. the page is rotated by the page's [Rotate](#) attribute and cropped using a bounding box. For example, the coordinate (0, 0) denotes the bottom left corner of the page.

The default bounding box used is the [CropBox](#). This can be changed by setting the [BoundingBox](#) property before calling the [Reset](#) method.

In both modes, the unit of the coordinate system is 1/72 inch.

6.3.19 SpaceFactor

Property (get, set): `Long SpaceFactor`
Default: `0.3`

This property can be used to get or set the distance between two characters that is required to insert a blank for text extraction. The default is `0.3`. This means any distance between two characters that are further apart as 0.3 times the width of the space character glyph in this font is interpreted as a new word. For text that is written very narrowly, this property should be decreased to avoid concatenation of words.

6.3.20 Text

Property (get): `Text Text`

Get the last read [Text](#) object. The text object is updated each time the [GetNextText](#) method is called or when [GetNextObject](#) returns [eText](#).

6.3.21 TextExtConfiguration

Property (get, set): Long [TextExtConfiguration](#)
Default: [eTECBreakTextState](#) + [eTECBreakGraphicsState](#) + [eTECBreakSpaceUnicode](#)

This property controls the way the text extraction algorithm works. When text is extracted, text objects are collected and merged into a single text. This property controls which text objects are merged. See the [TPDFTextExtract-Configuration](#) enumeration for a list of all possible options.

Recommended settings for different use cases:

- Text search or indexing, i.e., text formatting is not important.
 - Extract words individually: [eTECBreakSpaceUnicode](#)
 - Extract phrases: [eTECPosMergeSingleSpace](#) + [eTECPosMergeMultiSpace](#)
- Conversion of PDF content to another format, i.e., text formatting and exact positioning is crucial.
 - Usage of [RawString](#) or extracted fonts: [eTECBreakTextState](#) + [eTECBreakGraphicsState](#)
 - Other: [eTECBreakTextState](#) + [eTECBreakGraphicsState](#) + [eTECPosMergeSingleSpace](#)

6.3.22 TranslateSymbolic

Property (get, set): Boolean [TranslateSymbolic](#)
Default: [False](#)

Replace symbolic character from the Unicode custom range (0xF000..0xFFFF) with WinAnsi codes (0x00..0xFF).

Note: It is generally recommended to set this property to [True](#).

6.4 Image Interface

6.4.1 Alternates

Property (get): Variant [Alternates](#)

Get an array of alternate images (see [AlternateImage](#)). An image can have none, one, or multiple alternate images.

Interface note: Only in the COM interface does this property evaluate to an array of alternate images. In all other interfaces (C, .NET, and Java), this property returns an [AlternateArray](#) object through which alternate images can be accessed.

6.4.2 BitsPerComponent

Property (get): Integer `BitsPerComponent`

Return the number of bits that are used to represent a single color component of an image sample. The number of color components per image data sample can be retrieved through the image's color space interface.

6.4.3 ChangeOrientation

Method: Boolean `ChangeOrientation(TPDFOrientation iOrientation)`

Set the orientation of the image. This value has to be set prior to using the [Store](#) method. The orientation of the image can be retrieved from the [CTM](#) property.

6.4.4 ColorSpace

Property (get): ColorSpace `ColorSpace`

Get a the [ColorSpace](#) object of the image.

6.4.5 Compression

Property (get): TPDFCompression `Compression`

Get the compression used for the image in the PDF. See [TPDFCompression](#).

6.4.6 ConvertToRGB

Method: Boolean `ConvertToRGB()`

Convert the image to an RGB image. The conversion uses the image's color space to interpret the sample data. Calibrated color spaces are converted to RGB values according to the standard sRGB color space. Device color spaces are converted using pre-defined color profiles.

Returns:

True If the conversion was successful.

False Otherwise.

6.4.7 GetImage

Method: Variant `GetImage()`

Return the image from memory that was previously saved using the [StoreInMemory](#) method.

Returns:

The image as a 1-dimensional `Byte` array.

6.4.8 GetResolution

Method: Single `GetResolution(TransformMatrix Matrix)`

Return the resolution of an image on the page in DPI (dots per inch).

Parameter:

Matrix [`TransformMatrix`] The transformation matrix of the image (see [TransformMatrix](#)). This parameter is required since the image itself has no resolution. The resolution is the ratio between the size of the image and the size it uses on the page.

Returns:

The calculated resolution in DPI.

6.4.9 Height

Property (get): Long `Height`

Get the height of the image in pixels (also called samples). The unit of pixels can be converted to a distance unit such as inch, millimeter etc. using a resolution value, i.e. 72 DPI (dots per inch).

6.4.10 IsBitonal

Property (get): Boolean `IsBitonal`

This property is `True` when the image is bitonal.

6.4.11 IsColor

Property (get): Boolean [IsColor](#)

This property is **True** when the image is color.

6.4.12 IsMonochrome

Property (get): Boolean [IsMonochrome](#)

This property is **True** when the image is monochrome.

6.4.13 Mask

Property (get): Image [Mask](#)

Return the image's explicit mask if available. The mask image has one bit per pixel, where a one bit indicates an opaque pixel and a zero bit indicates a transparent pixel. The resolution of the image and the image mask may differ. The image mask is placed in the same unit square in user space as the associated image.

6.4.14 ObjNumber

Property (get): long [ObjNumber](#)

Get a unique number of this image resource. If the number is 0, the image resource occurs once only in the document (i.e. it is an inline image). If the number is larger than 0, the image resource may be used multiple times.

6.4.15 Samples

Property (get): Variant [Samples](#)

Return the image's data samples in a byte array. The sample data is ordered by line from top to bottom and within a line from left to right. The lines are byte-aligned. If the number of bits per component is less than one byte, then the samples are ordered beginning with the most significant bit first.

The interpretation of the sample data must be done according to the properties in the [ColorSpace](#) of the image.

6.4.16 SMask

Property (get, set): Image [SMask](#)

With this property, the soft mask of an image can be extracted. If the image has a soft mask, then this property provides an [Image](#) interface to the soft mask. An image soft mask is a monochrome image. Sample values in the image do not represent grayscale pixels; rather, they designate the alpha value of the image. A value of 0 ("black") designates a "fully transparent" place and a value of $2^{\text{BitsPerComponent}}-1$ ("white") "fully opaque". The resolution of the image and the image soft mask may differ. The image mask is placed in the same unit square in user space as the associated image.

6.4.17 Store

Method: `Boolean Store(String FileName, TPDFCompression Compression)`

Store the image to a file.

Parameters:

FileName [String] The name of the disk file including drive, path, or server string according to the operating system's naming rules. The type of the image is defined by its extension:

Recognized extensions	
Extension	File type
".bmp", ".dib", ".pbm", ".pgm", ".pnm", ".ppm"	Bitmap
".jpg", ".jpe"	JPEG
".jb2"	JBIG2
".jpx", ".jp2"	JPEG2000
".tif"	TIFF
".png"	PNG
".gif", ".jif"	GIF
".eps"	EPS

Use the second parameter [Compression](#) to indicate the compression type for TIFF files.

Compression [TPDFCompression] (optional) The compression type (for TIFF images). The default value is [eComprDefault](#), which for TIFF images is LZW compression.

Returns:

- True** The file has successfully been written.
- False** An error has occurred and the disk file is unusable.

6.4.18 StoreInMemory

Method: Boolean `StoreInMemory(String Extension, TPDFCompression Compression)`

Store the image in memory. The saved image can be retrieved using the [GetImage](#) method.

Parameters:

Extension [String] A file name extension that defines the type of image. See [Recognized extensions](#).

Compression [TPDFCompression] (optional) The compression type (for TIFF images). The default value is `eComprDefault`, which for TIFF images is LZW compression.

Returns:

True The image has successfully been saved.

False Otherwise.

6.4.19 Width

Property (get): Long `Width`

Return the width of the image in pixels (also called samples). The unit of pixels can be converted to a distance unit such as inch, millimeter etc. using a resolution value, i.e. 72 DPI (dots per inch).

6.5 Text Interface

6.5.1 BoundingBox

Property (get): Variant `BoundingBox`

Get the smallest rectangle that encloses the text as shown below:

The text bounding box is a rectangle, which encloses the four points Q1, Q2, Q3, Q4. The points Q1 and Q2 are 1/3 of the height below the baseline.

The text bounding box is defined by four values that represent the coordinate of the lower left and the upper right corner.

6.5.2 FontSize

Property (get): `Single` `FontSize`

Get the size of the font in points. The size can also be interpreted as the height of the text.

6.5.3 Length

[Deprecated] Property (get): `Short` `Length`

This property is superseded by [StringLength](#).

6.5.4 QuadPoints

Property (get, set): `TPDFVector[4]` `QuadPoints`

Get the quad points of the parallelogram that encloses the text. The first point in the array is always located at the lower left corner of the text. The remaining points correspond to the parallelogram points when traveling around the text in counter-clockwise direction. For example, the vector from the first to the second point always indicates the writing direction of the text. (See also the graphic in the description of [BoundingBox](#))

Note: This property is not available in the COM interface.

6.5.5 RawString

Property (get): `Variant` `RawString`

For “simple fonts”, this property returns the raw character codes from the PDF as a `Byte` array. For “CID fonts” ([IsCID](#)), this property is `Nothing`. If the [ExpandLigatures](#) property is not set, the length of the `RawString` is the same as the length of the [UnicodeString](#) and the character position vector applies to the `RawString` character codes as well.

The property [UnicodeString](#) always returns a string of Unicode characters. These Unicode strings result from the mapping of character codes to Unicode characters defined by the PDF specification and a set of heuristics. These Unicode strings may not be accurate. In some cases, you may have prior knowledge about this specific font and know the mapping of character codes to Unicode characters yourself. For example, you know that the creator has used the EBCDIC encoding. For this reason, the `RawString` property returns the string of character codes and allows you to apply your own mapping.

With [RawString](#), do not use the following [TextExtConfiguration](#) flags, because the Unicode that these flags work with may not be accurate:

- [eTECBreakSpaceUnicode](#)
- [eTECPosMergeSingleSpace](#)
- [eTECPosMergeMultiSpace](#)

6.5.6 Rotation

Property (get): [Single](#) [Rotation](#)

Get the rotation of the string in radians (rad). (2π rad = 360 °)

6.5.7 StringLength

Property (get): [Short](#) [StringLength](#)

Get the number of characters in the string.

6.5.8 UnicodeString

Property (get): [String](#) [UnicodeString](#)

Get the text as a Unicode UTF-16 encoded string. The number of bytes per character is a multiple of two. For most languages such as English, a character can be mapped to a single 16-bit Unicode value. Complex languages such as Chinese can return multiple 16-bit values per character. Some text strings cannot be correctly mapped or cannot be mapped at all. For example, the text strings are not correctly mapped if the PDF creator program did not use correct names for the character in the font encoding (see [Font](#)). The text strings cannot be mapped if the PDF creator program did not embed Unicode mapping information for a symbolic font.

The [HasUnicode](#) property of the [Font](#) object tells whether a text written with a specific font can be mapped to Unicode.

6.5.9 TextMatrix

[Deprecated] Property (get): [TransformMatrix](#) [TextMatrix](#)

Get the [TransformMatrix](#) object for this text.

Note: This is not the TextMatrix in the PDF graphic state. This is a matrix that incorporates the current transformation matrix (CTM), the text matrix, and other text properties such as text rise and font size.

6.5.10 Width

Property (get): Single [Width](#)

Get the width of the string in points.

6.5.11 XPos, YPos, Position

Property (get): Variant [XPos](#)

Property (get): Variant [YPos](#)

Property (get): [TPDFVector\[\]](#) [Position](#)

Interface note: The [XPos](#) and [YPos](#) properties are only present in the COM interface. All other interfaces provide the [Position](#) strings.

Get the horizontal and vertical position of the text's characters on the page in user coordinates. The return value is a 1-dimensional array holding the positions of all characters.

The length of the array is $\langle n \rangle + 1$, where $\langle n \rangle$ is the length of the text, i.e., the value of [StringLength](#). The zero-based index into the array has the following meaning:

0 represents the first character.

$\langle n \rangle - 1$ represents the last character.

$\langle n \rangle$ is calculated as the virtual position of where the next character would start. This position can be compared to the actual position of the next character to decide whether they belong to the same word or not.

[TPDFVector](#) represents a coordinate on the page and has two [x](#) and [y](#) properties of [Float](#) type.

6.6 GraphicsState Interface

Entries that have a complex structure such as a function are not retrievable with the 3-Heights® PDF Extract API. For example, these include "black generation functions" BG, "transfer functions" TR or "under-color-removal functions" UCR.

The 3-Heights® PDF Extract API has the ability to return colors in RGB or CMYK. If the requested color space is different from the actual color space in the PDF, the color conversion is done using color profiles.

For more information about graphic states, refer to the [PDF Reference 1.7](#) section "4.3 Graphic State".

6.6.1 AlphaIsShape

Property (get): Boolean [AlphaIsShape](#)

Get the AlphaIsShape flag. It is [True](#) if the soft mask contains shape values. It returns false for opacity.

6.6.2 BlendMode

Property (get): String BlendMode

Get the name of the blend mode. A blend mode can be "Normal", "Multiply", "Screen", and "Overlay".

6.6.3 CharSpacing

Property (get): Single CharSpacing

Get the current space between two characters of a text string as a single precision real number in text units.

6.6.4 CTM

Property (get): TransformMatrix CTM

Get the current [TransformMatrix](#). The transformation matrix describes the transformation of the graphic object's coordinates from user units to page units including the effect of the page's rotate attribute if requested (see method [Reset](#) of the [Content](#) interface).

6.6.5 DashArray

Property (get): Variant DashArray

Get the dash array of a line dash pattern. The line dash pattern controls the pattern of dashes and gaps used to stroke paths.

6.6.6 DashPhase

Property (get): Single DashPhase

Get the dash phase of a line dash pattern. The dash phase is the offset of the pattern and can be larger as the pattern itself.

6.6.7 FillAlphaConstant

Property (get): Single FillAlphaConstant

Get the alpha constant for filling path painting operations. See the [PDF Reference 1.7](#) Chapter 7 on transparency, and Section 4.5.3 for constant shape and constant opacity values that are linked to constant alpha values.

6.6.8 FillColorCMYK

Property (get): Long `FillColorCMYK`

Get the CMYK color quad that describes the color for filling operations. This value is obtained by converting the actual color by means of the [FillColorSpace](#). The CMYK quads are encoded using the following formula:

$$\text{Quad} = (((C \times 256) + M) \times 256 + Y) \times 256 + K.$$

If a color does not exist (e.g. with an uncolored pattern), then **-1** is now returned.

The CMYK values can be reconstructed as follows:

Hexadecimal Quad = 0xCCMMYYKK, where CC is the byte for the cyan value in the range from 0x00 to 0xFF, MM is magenta, YY is yellow, KK is key (black).

Decimal To retrieve the values for cyan, magenta, yellow, and key, apply the following formulas (VB code taking into account negative values, using integer-division `\` and bitwise and `And`):

```
Quad = PDFPARSERLib.GraphicsState.FillColorCMYK
t = Quad And &H7FFFFFFF C = t \ 65536
M = (t \ 256) And 255
Y = (t \ 256) And 255
K = t And 255
If Quad < 0 Then C = C Or &H80
```

There are also other ways to retrieve these values than using the above formulas.

6.6.9 FillColorRGB

Property (get): Long `FillColorRGB`

Get the RGB color triple that describes the color for filling operations. This value is obtained by converting the actual color by means of the [FillColorSpace](#). The RGB triples are encoded using the following formula:

$$\text{Triple} = ((B \times 256) + G) \times 256 + R.$$

If a color does not exist (e.g. with an uncolored pattern), then **-1** is now returned.

Hexadecimal Triple = 0xBBGGRR, where BB is the byte for the blue value in the range from 0x00 to 0xFF, GG is green, RR is red.

Decimal To retrieve the values for blue, green, and red, apply the following formulas (integer-division `\` and bitwise and `And`):

```
Triple = PDFPARSERLib.GraphicsState.FillColorRGB
B = Triple \ 65536
G = (Triple \ 256) And 255
R = Triple And 255
```

```
Example:  
Triple = 8388736 (purple)  
B = 8388736 \ 65536 = 128  
G = (8388736 \ 256) And 255 = 0  
R = 8388736 And 255 = 128
```

There are also other ways to retrieve these values than using the above formulas.

6.6.10 FillColorSpace

Property (get): ColorSpace FillColorSpace

Get the current [ColorSpace](#) that is used for filling operations. The color space is used to compute color values of the [FillColorCMYK](#) and [FillColorRGB](#) properties.

6.6.11 FillOverprintFlag

Property (get): Boolean FillOverprintFlag

Get the overprint flag for painting operations other than stroking. See the [PDF Reference 1.7](#) Section 4.5.6 for more information about overprint.

6.6.12 FlatnessTolerance

Property (get): Single FlatnessTolerance

Get the flatness tolerance. It must be a positive number. A small number means higher precision.

6.6.13 Font

Property (get): Font Font

Get an interface to the text's font object that describe the character encoding and the shape of the character glyphs.

6.6.14 FontSize

Property (get): Single FontSize

Get the current font size for text strings as a single precision real number in text units. It does not include any scaling factors from coordinate transforms such as from the current transform matrix or the text matrix. To obtain the font size in page units, the values of the current text matrix have to be examined.

6.6.15 HorizontalScaling

Property (get): Single `HorizontalScaling`

Get the current horizontal scaling factor that describes the amount of horizontal stretching of a text string. A value of greater than **1.0** stretches the string, whereas a value of less than **1.0** lets the string appear as condensed.

6.6.16 Leading

Property (get): Single `Leading`

Get the current leading (line spacing) of a text string as a single precision number in text units.

6.6.17 LineCap

Property (get): Short `LineCap`

Get the line cap style. The line cap style specifies the shape to be used at the end of open sub-paths and dashes when they are stroked.

- 0** Butt cap
- 1** Round cap
- 2** Projecting square cap

6.6.18 LineJoin

Property (get): Short `LineJoin`

Get the line join style. The line join style specifies the shape to be used at the corners of paths that are stroked.

- 0** Miter join
- 1** Round join
- 2** Bevel join

6.6.19 LineWidth

Property (get): Single `LineWidth`

Get the line width as a single precision real number in user units.

6.6.20 MiterLimit

Property (get): Single [MiterLimit](#)

Get the miter limit. The miter limit imposes a maximum on the ratio of the miter length to the line width, which can be fairly large when two line segments meet at a sharp angle. When the limit is exceeded, the join is converted from a miter to a bevel.

6.6.21 OverprintMode

Property (get): Short [OverprintMode](#)

Get the overprint mode. See the [PDF Reference 1.7](#) Section 4.5.6 for more information about overprint.

6.6.22 RenderingIntent

Property (get): String [RenderingIntent](#)

Get the name of the rendering intent.

6.6.23 SmoothnessTolerance

Property (get): Single [SmoothnessTolerance](#)

Get the smoothness tolerance. The values are in the range `[0.0, 1.0]` where `1.0` corresponds to 100%.

6.6.24 SpaceWidth

Property (get): Float [SpaceWidth](#)

Get the width of the space character in text space. To convert to page user units, transform this value using the text's transformation matrix. The [SpaceWidth](#) property can be used to implement your own word breaking algorithm. For more information about this, see the [TextExtConfiguration](#) and [SpaceFactor](#) properties.

6.6.25 StrokeAdjustment

Property (get): Boolean [StrokeAdjustment](#)

Get the flag for the automatic stroke adjustment. The flag specifies whether to compensate for possible rasterization effects when stroking a path with a line width that is small relative to the pixel resolution of the output device. See [PDF Reference 1.7](#) Section 6.5.4 for more information about stroke adjustment.

6.6.26 StrokeAlphaConstant

Property (get): Single [StrokeAlphaConstant](#)

Get the current alpha constant for stroking path painting operations. See the [PDF Reference 1.7](#) Chapter 7 on transparency, and Section 4.5.3 for constant shape and constant opacity values that are linked to constant alpha values.

6.6.27 StrokeColorCMYK

Property (get): Long [StrokeColorCMYK](#)

Get the CMYK color quad that describes the color for stroking operations. This value is obtained by converting the actual color by means of the [StrokeColorSpace](#). The CMYK quads are encoded using the following formula:

Quad = (((C × 256) + M) × 256 + Y) × 256 + K.

6.6.28 StrokeColorRGB

Property (get): Long [StrokeColorRGB](#)

Get the RGB color triple that describes the color for stroking operations. This value is obtained by converting the actual color by means of the [StrokeColorSpace](#). The RGB triples are encoded using the following formula:

Triple = ((R × 256) + G) × 256 + B.

6.6.29 StrokeColorSpace

Property (get): ColorSpace [StrokeColorSpace](#)

Get the current [ColorSpace](#) that is used for stroking operations. The color space is used to compute color values of the [StrokeColorCMYK](#) and [StrokeColorRGB](#) properties.

6.6.30 StrokeOverprintFlag

Property (get): Boolean [StrokeOverprintFlag](#)

Get the overprint flag for stroking painting operations. See the [PDF Reference 1.7](#) Section 4.5.6 for more information about overprint.

6.6.31 TextKnockout

Property (get): Boolean `TextKnockout`

Get the text knockout flag. This Boolean flag determines the behavior of overlapping glyphs within a text object in the transparent imaging model.

6.6.32 TextRenderingMode

Property (get): Short `TextRenderingMode`

Get a value that indicates whether the text should be stroked, filled, used as a clip path, or some combination of the three. The meaning of the values in detail is:

- 0 Fill text.
- 1 Stroke text.
- 2 Fill, then stroke text.
- 3 Do not fill nor stroke text (invisible).
- 4 Fill text and add path for clipping.
- 5 Stroke text and add path for clipping.
- 6 Fill, then stroke text, and add path for clipping.
- 7 Add path for clipping.

6.6.33 TextRise

Property (get): Single `TextRise`

Get a single precision real number in un-scaled text units that indicates the amount by which the base line of the text is moved up or down. It is most commonly used to display subscripts and superscripts.

6.6.34 WordSpacing

Property (get): Single `WordSpacing`

Get the current space between two words of a text string as a single precision real number in text units. (For more information about the graphic state, see [PDF Reference 1.7](#), section 4.3.)

6.7 Font Interface

6.7.1 Ascent

Property (get): Single `Ascent`

Get the ascent value. This value represents the maximum height above the baseline reached by the glyphs in the font, excluding the height of glyphs for accented characters.

6.7.2 AvgWidth

Property (get): Single `AvgWidth`

Get the average width of the glyphs in the font.

6.7.3 BaseName

Property (get): String `BaseName`

Get the font name.

6.7.4 CapHeight

Property (get): Single `CapHeight`

Get the height of the top of flat capital letters, measured from the baseline.

6.7.5 Charset

Property (get): String `Charset`

Get a string listing the character names defined in a font subset. This property is only useful for Type1 fonts.

6.7.6 Descent

Property (get): Single `Descent`

Get the descent value. This negative number represents the maximum depth below the baseline reached by the glyphs in the font.

6.7.7 Encoding

Property (get): Variant Encoding

Method: String Encoding(Long charIndex)

Get the glyph name of characters.

Interface note: The COM interface provides only the **property Encoding**. In this case, the returned type is an array of length 256 of **Strings**. The other interfaces provide only the **method Encoding** and the return type is a **String**. The **charIndex** parameter specifies the character for which to get the glyph name. This value must be between 0 and 255.

6.7.8 Flags

Property (get): Long Flags

Get the flags of the font. The flags are listed the following table. Bit positions within the flag word are numbered from 1 (low-order) to 32 (high-order).

Bit position	Name	Meaning
1	FixedPitch	All glyphs have the same width.
2	Serif	Glyphs have serifs.
3	Symbolic	The font contains characters outside the standard Latin character set.
4	Script	Glyphs resemble cursive handwriting.
6	NonSymbolic	Font uses standard Latin character set or a subset of it.
7	Italic	Glyphs are italic.
17	AllCap	Font has no lowercase letters.
18	SmallCap	Lowercase letters are small uppercase letters.
19	ForceBold	If set, bold glyphs are painted bold even at very small text size.

6.7.9 FontBBox

Property (get): Variant FontBBox

Get the font bounding box. The font bounding box is the rectangle in which all glyphs would fit, if they were placed on top of each other with their origins at the same point.

6.7.10 FontFile

Property (get): Variant FontFile

Get the font file as a [Byte](#) array. This property is **Nothing** if the font has no embedded font file.

6.7.11 FontFileType

Property (get): Short FontFileType

Get the type of the font file. See [PDF Reference 1.7](#) section “5.7 Font descriptors” for more information.

Value	PDF font file type	Description
0	—	This font has no font file.
1	FontFile	Type 1 font.
2	FontFile2	TrueType font.
3	FontFile3	The type of the font is determined by Type .

6.7.12 HasUnicode

Property (get): Boolean HasUnicode

This property tells whether the font provides Unicode characters. If this property is **False**, then text written with this font is not extractable. In other words, the [UnicodeString](#) property of the [Text](#) contains not Unicode characters, but directly the character IDs.

6.7.13 IsCID

Property (get): Boolean IsCID

This property is **True** if the font is a CID Font.

6.7.14 ItalicAngle

Property (get): Single `ItalicAngle`

Get the counter-clockwise angle of the dominant vertical strokes of the font.

6.7.15 Leading

Property (get): Single `Leading`

Get the desired spacing between baselines of consecutive lines of text.

6.7.16 MaxWidth

Property (get): Single `MaxWidth`

Get the maximum width of the glyphs in the font.

6.7.17 MissingWidth

Property (get): Single `MissingWidth`

Get the value of the width which is used for character codes for which the glyph is missing in the font directory's Width array.

6.7.18 StemH, StemV

Property (get): Single `StemH`

Property (get): Single `StemV`

These properties provide the vertical and horizontal thickness of the dominant vertical and horizontal stems of the glyphs in the font.

6.7.19 Type

Property (get): Single `Type`

Get the font type either of the following strings: `"Type1"`, `"Type1C"`, `"TrueType"`, `"Type3"`, or `"Unknown"`.

6.7.20 Widths

Property (get): Variant Widths

Get an array of `Float`, which contains the widths of the glyphs.

6.7.21 WMode

Property (get): Long WMode

Get the writing mode for this font. `0` means “horizontal writing mode” and `1` means “vertical writing mode”.

The value of the property has both an effect on the font’s glyph positioning and glyph appearance. For example, parentheses are usually horizontal with WMode `0` and vertical with WMode `1`.

6.7.22 XHeight

Property (get): Single XHeight

Get the maximum height of flat non-ascending lowercase letters (such as the letter x) measured from the baseline.

(For further information about font descriptors, see [PDF Reference 1.7](#), section 5.7.)

6.8 ColorSpace Interface

6.8.1 BaseColorSpace

Property (get): ColorSpace BaseColorSpace

Get the base [ColorSpace](#) if it exists. See also [Lookup](#).

6.8.2 ColorantName

Property (get): Variant ColorantName

Get the name of the colorant.

Interface note: COM: A variant containing an array of strings is returned. These strings represent the name of the colorants of the color space. In an RGB color space, these are "Red", "Green", and "Blue".
C, .Net: An additional parameter is passed, which defines the index of the colorant. Instead of an array containing all strings, a single string is returned, e.g. "Red".

6.8.3 ComponentsPerPixel

Property (get): Integer ComponentsPerPixel

Return the number of components per pixel.

6.8.4 HighIndex

Property (get): Short HighIndex

Get the highest possible index value for indexed colors. It is 0 when no indexed color space is used.

6.8.5 IsColor

Property (get): Boolean IsColor

This property is True when the color space has more than one channel.

6.8.6 IsIndexed

Property (get): Boolean IsIndexed

This property is True when the image uses indexed colors.

6.8.7 IsMonochrome

Property (get): Boolean IsMonochrome

This property is True when the color space is monochrome.

6.8.8 Lookup

Property (get): Variant Lookup

Get the color lookup table as a byte array. The lookup table is only present if the color spaced is an indexed (palletted) color space. In other words, if [IsIndexed](#) is **True**.

The lookup table contains color values in the [BaseColorSpace](#). For example, if the base color space is an RGB color space, then the table contains bytes $R_0\ G_0\ B_0\ R_1\ G_1\ B_1\ \dots\ R_h\ G_h\ B_h$, where h is the value of [HighIndex](#). The length of the table in bytes hence is $(h + 1) \cdot c$, where c is the value of [ComponentsPerPixel](#). Refer to the [PDF Reference 1.7](#) Section "4.5.5 Special Color Spaces" for more information about indexed color spaces.

6.8.9 Name

Property (get): String Name

Get the name of the color space as string, for example **"DeviceGray"**, **"DeviceRGB"**, or **"Indexed"**.

6.9 TransformMatrix Interface

6.9.1 a, b, c, d, e, f

Property (get): Single a
Property (get): Single b
Property (get): Single c
Property (get): Single d
Property (get): Single e
Property (get): Single f

The transformation matrix in PDF is specified by six numbers. All information about orientation, rotation, scaling, skewing, and translation can be calculated based on these six numbers. However, the 3-Heights® PDF Extract API also provides properties that compute these values.

The actual matrix is $M = \begin{bmatrix} a & b & 0 \\ c & d & 0 \\ e & f & 1 \end{bmatrix}$

This matrix is used to define a transformation of a vector $[x\ y\ 1]$ to a vector $[x'\ y'\ 1] = [x\ y\ 1] \cdot M$, where (x, y) is the original point and (x', y') is the transformed point on the page. In the following, the matrix is represented by the array $[a\ b\ c\ d\ e\ f]$, holding the coefficients **a** to **f**.

The values **e** and **f** represent the translation. In a matrix $[1\ 0\ 0\ 1\ e\ f]$, **e** is the distance on the x-axis from the left side page border, **f** is the distance on the y-axis from the bottom. The point (0,0) is in the lower left corner, on an page with a size of A4 portrait, (595,842) is in the upper right corner.

The scale factor in a matrix $[a\ 0\ 0\ d\ 0\ 0]$ can be obtained from the **a** and **d** values for x and y scaling, respectively. With respect to fonts, **d** represents the font size of horizontal text.

A rotation of the axis by an angle α counter clockwise is produced by a matrix $[\cos\alpha\ \sin\alpha\ -\sin\alpha\ \cos\alpha\ 0\ 0]$.

More detailed information can be found in the [PDF Reference 1.7](#) sections “4.2.2 Common transformations” and “4.2.3 Transformation Matrices”.

6.9.2 Orientation

Property (get): `TPDFOrientation Orientation`

Return the orientation rounded to the next 90°. The orientation is an enumeration with eight different values (rotation times flipping). See [TPDFOrientation](#).

6.9.3 Rotation

Property (get): `Single Rotation`

Get the rotation angle of the matrix counter clockwise. This is equal to the minimum of [XSkew](#), [YSkew](#) and [-XSkew](#), [YSkew](#).

6.9.4 XScaling, YScaling

Property (get): `Single XScaling`

Property (get): `Single YScaling`

Get the horizontal and vertical scaling factor.

6.9.5 XSkew, YSkew

Property (get): `Single XSkew`

Property (get): `Single YSkew`

Get the x and y-axis skewing. The transformation matrix $\begin{bmatrix} 1 & \tan\alpha & \tan\beta & 1 & 0 & 0 \end{bmatrix}$ skews the x-axis by α and the y-axis by β . Skewing sometimes is used to transform a regular font to italic.

6.9.6 XTranslation, YTranslation

Property (get): `Single XTranslation`

Property (get): `Single YTranslation`

Get the translation in horizontal and vertical direction. These are the same values as returned by the [a](#), [b](#), [c](#), [d](#), [e](#), [f](#) and [a](#), [b](#), [c](#), [d](#), [e](#), [f](#) properties.

6.10 AlternateImage Interface

6.10.1 DefaultForPrinting

Property (get): Boolean `DefaultForPrinting`

This property is **True** if the alternate image is set as default for printing.

6.10.2 Image

Property (get): Image `Image`

Get an [Image](#) interface to the alternate image.

6.11 AlternateArray Interface

Interface note: This interface exists only in the C, the .NET, and the Java interfaces. In the COM interface, the [Alternates](#) property returns directly an array of alternate images. In Java, the name of this interface is [AlternateImageArray](#).

6.11.1 Count

Property (get): Integer `Count`

Get the size of the array, i.e., the number of alternate images in the array.

6.11.2 GetElement

Method: `GetElement(Integer Index)`

Use this method to retrieve a [AlternateImage](#) from the array.

Parameter:

Index [Integer] The zero-based index into the array.

6.12 Annotation Interface

For more information about PDF annotations, refer to the [PDF Reference 1.7](#) section “8.4 Annotations”.

6.12.1 AttachedFile

Property (get): [EmbeddedFile](#) [AttachedFile](#)

Get the [EmbeddedFile](#) attached to this annotation. This property is meaningful for FileAttachment annotations only. The [AttachedFile](#) may not have an embedded file stream, but reference an external file via the [FileName](#) property only.

6.12.2 Color

Property (get): [Long](#) [Color](#)

Get to color of the annotation.

6.12.3 Contents

Property (get): [String](#) [Contents](#)

Get the content of the annotation.

6.12.4 Date

Property (get): [Date](#) [Date](#)

Get the date of the annotation. The used format is: #dd.mm.yyyy hh:mm:ss#

6.12.5 Dest

Property (get): [Destination](#) [Dest](#)

Get the [Destination](#) of a link annotation. This entry is permitted if an A (action) entry is present.

6.12.6 Flags

Property (get): Long [Flags](#)

Get the flags of the annotation as 32 bit integer. The following bit-positions are possible:

- 1 Invisible
- 2 Hidden (PDF 1.2 and later)
- 3 Print (PDF 1.2 and later)
- 4 NoZoom (PDF 1.3 and later)
- 5 NoRotate (PDF 1.3 and later)
- 6 NoView (PDF 1.3 and later)
- 7 ReadOnly (PDF 1.3 and later)
- 8 Locked (PDF 1.4 and later)
- 9 ToggleNoView (PDF 1.5 and later)

6.12.7 IsMarkup

Property (get): Boolean [IsMarkup](#)

Decides whether the annotation is a markup annotation. The following annotations are considered markup annotations:

- Free text annotations
- Annotations that have a pop-up window that may display text
- Sound annotations

6.12.8 Name

Property (get): String [Name](#)

Get the name of the annotation as string.

6.12.9 Rect

Property (get): Variant [Rect](#)

Get the rectangle of the annotation as an array [[x1](#), [y1](#), [x2](#), [y2](#)]. Where ([x1](#), [y1](#)) is the lower left corner of the annotation and ([x2](#), [y2](#)) the upper right corner. The coordinates are raw PDF coordinates. To calculate where the rectangle is positioned on the page as displayed by a viewer, the rectangle must be cropped using the page's [CropBox](#) and rotated using the [Rotate](#) attribute.

6.12.10 Subj

Property (get): String Subj

Get the text representing a short description of the subject. This property is only available for mark-up annotations (requires PDF 1.5 or later).

6.12.11 Subtype

Property (get): String Subtype

Get the type of the annotation as string such as "Widget", "Square", "PopUp", "FreeText", "Ink", etc.

6.12.12 TextLabel

Property (get): String TextLabel

Get the text label of the annotation as string. This label is usually used for the name of the author.

6.12.13 QuadPoints

Property (get): Variant QuadPoints

Get the quad points of a text markup or a link annotation. The return value is an array of floating-point numbers that represent x- and y-values of the quad points: $x_1\ y_1\ x_2\ y_2\ \dots\ x_n\ y_n$, where n is the number of quad points. For other annotation types, this property is **Nothing**. If the text markup or link annotation has no quad points, then the points of the bounding rectangle are returned.

6.12.14 URI

Property (get): String URI

Get the URI entry of the annotation as string if present.

6.12.15 Vertices

Property (get): Variant Vertices

Get the vertices of a polygon or polyline annotation. The return value is an array of floating-point numbers that represent x- and y-values of the vertices: $x_1\ y_1\ x_2\ y_2\ \dots\ x_n\ y_n$, where n is the number of vertices in the polygon or polyline. For other annotation types or if the polygon/polyline annotation is empty, this property is **Nothing**.

6.13 OutlineItem Interface

6.13.1 Count

Property (get): Long Count

Get the number of children of the current outline. A negative number means the child tree is not opened.

6.13.2 Dest

Property (get): Destination Dest

Get this outline's [Destination](#).

6.13.3 Title

Property (get): String Title

Get the title of the outline.

6.14 Destination Interface

For more information about PDF destinations, refer to the [PDF Reference 1.7](#) section "8.2.1 Destinations".

Note: The [Bottom](#), [Left](#), [Right](#), and [Top](#) properties of the [Destination](#) interface have different meanings depending on the type of the destination. The coordinates are raw PDF user space coordinates.

6.14.1 Bottom

Property (get): Single Bottom

Get the bottom value.

6.14.2 Left

Property (get): Single Left

Get the left value.

6.14.3 PageNo

Property (get): Long PageNo

Get the target page number

6.14.4 Right

Property (get): Single Right

Get the right value.

6.14.5 Top

Property (get): Single Top

Get the top value.

6.14.6 Type

Property (get): String Type

Get the type of the destination, such as "XYZ", "Fit", "FitH", "FitR", etc.

6.14.7 Zoom

Property (get): Single Zoom

Get the zoom value of the destination. A value of 0 means the zoom level is left unchanged. A value of 1 means 100% magnification.

6.15 Ocg Interface

The optional content group (OCG) interface allows you to list OCGs (also known as "layers") and their properties.

The concept of OCGs in PDF differs substantially from the simple layer paradigm found in graphics editing programs. There is no one-to-one correspondence between graphics objects in PDF and OCGs. Instead, the object visibility is determined by a Boolean function dependent on the state of any number of OCGs. For example, a path could be visible only if OCG "A" is On and OCG "B" is Off.

The functionality of OCGs are described in depth in ISO 32000-1, section 8.11.4 or in the [PDF Reference 1.7](#), section 4.10. OCGs are supported in PDF 1.5 or later. To extract content from all layers, the [IgnoreOCM](#) property should be set to **True**.

For more background information including a sample, see [Optional content \(Layers\)](#).

6.15.1 Label

Property (get): Boolean **Label**

Flag that indicates whether this is an OCG or a label. Labels are used to label groups of OCGs in the hierarchy. Setting their visibility has no effect.

6.15.2 Level

Property (get): Long **Level**

In user interfaces OCGs can be shown in a tree. The property level indicates the hierarchy level of the OCG in that tree. OCG with Level 0 is a top level OCG. Level -1 means that the OCG is not part of the hierarchy, it should not be presented to the user. Parent elements in the OCG hierarchy can be labels or OCGs. If the level of a label B is higher than its predecessor A, B is the parent element of the following objects of the same level as B. If the level of an OCG B is higher than its predecessor OCG A, A is the parent of the following objects of the same level as B. The hierarchy reflects actual nesting of OCGs in the content. Setting the visibility of an OCG to true only has an effect, if the visibilities of all its parents are set to true.

6.15.3 Name

Property (get): String **Name**

Get the name of the OCG.

6.15.4 Visible

Property (get, set): Boolean **Visible**

Get or set the visibility of the OCG. This property controls the extraction of content objects. The default value is the one configured in the PDF document.

Although invisible paths do not generate any marks on the page, they still have an effect on the graphics state. For example, their effect on the current drawing position and the clipping region does not change. Therefore, all paths

are “active” and extracted regardless of their visibility. Invisible paths just use the end path operator n, instead of a filling or stroking operator.

Examples:

ID	OCGs	Level	Hierarchy
0	OCG A	0	- OCG A
1	OCG B	0	- OCG B
2	OCG B1	1	-- OCG B1
3	OCG B2	1	-- OCG B2
4	OCG C	-1	hidden: OCG C

ID	OCGs/Labels	Level	Hierarchy
0	OCG A	0	- OCG A
1	Label B	1	- Label B
2	OCG B1	1	-- OCG B1
3	OCG B2	1	-- OCG B2
4	Label C	1	- Label C
5	OCG C1	1	-- OCG C1
6	OCG D	0	- OCG D

6.16 PDFObject Interface

This interface represents a basic PDF object. More information on these types of objects can be found in section 3.2 of the [PDF Reference 1.7](#). The [PDFObject](#) interface represents an object, which can be one of eight types. Depending on its type, different methods and properties should be used.

Note: Indices of dictionary and array objects are zero based.

Note: If PDF objects are traversed recursively, it must be ensured the program does not end up in an endless-loop for cyclical structures.

There is a Java sample PdfObjExt.java available that shows how to use this interface.

6.16.1 Begin, GetNext, End

Property (get): Long [Begin](#)

Property (get): Long [End](#)

Method: [GetNext](#)(Long i)

Applies to dictionaries.

Iterator: The [Begin](#) property, [GetNext](#) method, and [End](#) property can be used to traverse a dictionary object. [GetKey](#) and [GetValue](#) return the key and value of an element in the dictionary.

Example: C#

```
for (int i = dict.Begin; i != dict.End; i = dict.GetNext(i))
```

```
{ /* do something */ }
```

6.16.2 BooleanValue

Property (get): Boolean [BooleanValue](#)

Get the Boolean value of a Boolean object.

6.16.3 Dispose, DestroyObject

.NET API All objects retrieved from the API are destroyed when the document is closed. However, it is recommended that you to use [Dispose](#) as soon as possible to save memory.

Java and C/C++ API The [TPdfExpaPDFObject](#) objects must always be deleted using [ExpaPDFObjectDestroyObject](#).

6.16.4 GetElement

Method: [PDFObject](#) [GetElement](#)(Long [i](#))

Applies to arrays. Return a [PDFObject](#) for the [i](#)-th value in the array.

6.16.5 GetEntry

Method: [PDFObject](#) [GetEntry](#)(String [Key](#))

Applies to dictionaries. Return a [PDFObject](#) that corresponds to the [Key](#) in the dictionary.

6.16.6 GetKey

Method: String [GetKey](#)(Long [i](#))

Applies to dictionaries. Return the string representation of the [i](#)-th key in the dictionary.

See also [GetValue](#).

6.16.7 GetStream, StreamMem

Property (get, set): Variant [StreamMem](#)

Method: Long [GetStream](#)(String [FileName](#))

Applies to indirect objects. Return the indirect object's stream, if present. If the object is an image, the compressed stream is returned. Otherwise, the stream is decompressed.

6.16.8 GetValue

Method: `PDFObject GetValue(Long i)`

Applies to dictionaries. Return a `PDFObject` that corresponds to the `i`-th value in the dictionary.

See also `GetKey`.

6.16.9 IntegerValue

Property (get): `Long IntegerValue`

Get the integer value of a numeric object.

6.16.10 Name

Property (get): `String Name`

Get the character sequence of a name object. The string is zero terminated.

6.16.11 ObjectNumber

Property (get): `Long ObjectNumber`

Applies to indirect objects. Get the object number.

6.16.12 RealValue

Property (get): `Double RealValue`

Get the real value of a numeric object.

6.16.13 Size

Property (get): `Long Size`

Applies to arrays. Get the size of the array.

6.16.14 StringValue

Property (get): Variant `StringValue`

Get the content of a string object as byte array.

6.16.15 TextStringValue

Property (get): String `TextStringValue`

Get the correctly decoded value of a PDF string object as a string.

Note: In PDF, string objects can be used for any binary data. This property only yields correct strings for PDF string objects that represent human-readable text strings. See the [PDF Reference 1.7](#) to determine the string objects that can safely be considered as text strings.

6.16.16 Type

Property (get): `TPDFObjectType` `Type`

Get the type of the object. See [TPDFObjectType](#).

6.17 EmbeddedFile Interface

6.17.1 AssociationRelationship

Property (get): String `AssociationRelationship`

The file's association relationship.

6.17.2 CheckSum

Property (get): Variant `CheckSum`

Get the 16-byte MD5 checksum.

6.17.3 CreationDate

Property (get): String `CreationDate`

Get the creation date.

6.17.4 Description

Property (get): String `Description`

The file's description.

6.17.5 FileName

Property (get): String `FileName`

Get the embedded file's path. If the embedded file has no associated file stream, (the [Store](#) and [StoreInMemory](#) functions return false), the `FileName` property references an external file.

6.17.6 IsInitialDocument

Property (get): Boolean `IsInitialDocument`

Whether this is the initial document of the collection.

6.17.7 MediaType

Property (get): String `MediaType`

Get the media type (MIME type) of the embedded file as a string.

6.17.8 ModDate

Property (get): String `ModDate`

Get the modification date.

6.17.9 Store

Method: Boolean `Store(String Path)`

Store the embedded file to disk.

Parameter:

Path [`String`] The file name and path, where the document is stored.

Returns:

True If the operation completed successfully.

False Otherwise.

6.17.10 StoreInMemory

Method: Variant `StoreInMemory()`

Store the embedded file in memory.

Returns:

The embedded file as a byte array.

6.18 DPartRoot Interface

This interface is used to access the document parts information of a PDF 2.0 or a PDF/VT. See the ISO 32000-2 and ISO 16612-2 standards for more information on document parts.

6.18.1 NodeNameCount, NodeName

Property (get): Integer `NodeNameCount`

Method: String `NodeName(Integer index)`

Access the document parts' node name list by querying the length of this list with `NodeNameCount` and getting individual elements with `NodeName` using the zero-based `index`.

Each name in this list corresponds to a document part node level of the document part hierarchy beginning with the `RootNode`.

If no node name list is present, then `NodeNameCount` is 0.

6.18.2 RecordLevel

Property (get): Integer [RecordLevel](#)

Get the zero-based level of the document part hierarchy at which each [DPartNode](#) corresponds to a component of the document.

6.18.3 RootNode

Property (get): [DPartNode](#) [RootNode](#)

Get a [DPartNode](#) interface to the root node in the document parts hierarchy of nodes.

6.19 DPartNode Interface

6.19.1 ChildrenCount, Child

Property (get): Integer [ChildrenCount](#)

Method: [DPartNode](#) [Child](#)(Integer [index](#))

Access this node's children by querying their count with [ChildrenCount](#) and accessing individual elements with [Child](#) using the zero-based [index](#). If no children are present then [ChildrenCount](#) is [0](#).

A document part node can either have children or an associated [PageRange](#), but not both.

6.19.2 DPM

Property (get, set): [PDFObject](#) [DPM](#)

Use this property to extract the document part metadata (DPM) associated with this node.

For document parts, the metadata takes the form of PDF objects. See [PDFObject](#). This property returns the DPM dictionary, which may contain as entry values any other PDF objects of text string, date string, array, dictionary, boolean, integer, or real type. This means that for PDF string objects, you can safely access the text string by means of the [TextStringValue](#) property.

6.19.3 PageRange

Property (get, set): [PageRange](#) [PageRange](#)

Get the page range, i.e. the first and last page number (one-based), associated with this document part node. If this node has no associated page range, then this property evaluates to [Nothing](#).

A document part node can either have children ([ChildrenCount](#), [Child](#)) or an associated page range, but not both.

6.20 Enumerations

Note: Depending on the interface, enumerations may have “TPDF” as prefix (COM, C), “PDF” as prefix (.NET), or no prefix at all (Java).

6.20.1 TPDFCompliance Enumeration

TPDFCompliance table

TPDFCompliance	
ePDF11	PDF Version 1.1
ePDF12	PDF Version 1.2
ePDF13	PDF version 1.3
ePDF14	PDF version 1.4 (corresponds to Acrobat 5)
ePDF15	PDF version 1.5
ePDF16	PDF version 1.6 (corresponds to Acrobat 7)
ePDF17	PDF version 1.7, ISO 32000-1
ePDF20	PDF version 2.0, ISO 32000-2
ePDFA1a	PDF/A 1a, ISO 19005-1, conformance level A
ePDFA1b	PDF/A 1b, ISO 19005-1, conformance level B
ePDFA2a	PDF/A 2a, ISO 19005-2, conformance level A
ePDFA2b	PDF/A 2b, ISO 19005-2, conformance level B
ePDFA2u	PDF/A 2u, ISO 19005-2, conformance level U
ePDFA3a	PDF/A 3a, ISO 19005-3, conformance level A
ePDFA3b	PDF/A 3b, ISO 19005-3, conformance level B
ePDFA3u	PDF/A 3u, ISO 19005-3, conformance level U

Note that only the values listed above are supported.

6.20.2 TPDFCompression Enumeration

TPDFCompression table

TPDFCompression	Description
eComprRaw	No compression
eComprJPEG	Joint Photographic Expert Group
eComprFlate	Flate compression
eComprLZW	Lempel-Ziv-Welch
eComprGroup3	CCITT Fax Group 3
eComprGroup3_2D	CCITT Fax Group 3 2D
eComprGroup4	CCITT Fax Group 4
eComprJBIG2	Joint Bi-level Image Experts Group
eComprJPEG2000	JPEG2000
eComprUnknown	Unknown compression
eComprDefault	Apply a default compression which suites the color space of the image.

Note: Not all image formats/color depths support all compression types.

6.20.3 TPDFContentObject Enumeration

See also [GetNextObject](#) method.

Value	Description
eNone	No content object. The end of the content has been reached.
eText	Text object
eImage	Image object
ePath	Path object
eSave	Save the current graphics state
eRestore	Restore the current graphics state
eBeginOCM	Start of a sequence of objects, whose visibility is defined by an optional content membership (OCM) string.
eEndOCM	End of OCM sequence

6.20.4 TPDFErrorCode Enumeration

All `TPDFErrorCode` enumerations start with a prefix, such as `PDF_`, followed by a single letter which is one of `S`, `E`, `W` or `I`, an underscore, and a descriptive text.

The single letter gives an indication of the severity of the error. These are: Success, Error, Warning, and Information. In general, an error is returned if an operation could not be completed. A warning is returned if the operation was completed, but problems occurred in the process.

A list of all error codes is available in the C API header file `bseerror.h`, the javadoc documentation of `com.pdftools.NativeLibrary.ERRORCODE`, and the .NET documentation of `Pdftools.Pdf.PDFErrorCode`. Note that only a few are relevant for the 3-Heights® PDF Extract API, most of which are listed here:

TPDFErrorCode table

TPDFErrorCode	Description
<code>PDF_S_SUCCESS</code>	The operation was completed successfully.
<code>LIC_E_NOTSET</code> , <code>LIC_E_NOTFOUND</code> , ...	Various license management related errors.
<code>PDF_E_FILEOPEN</code>	Failed to open the file.
<code>PDF_E_FILECREATE</code>	Failed to create the file.
<code>PDF_E_PASSWORD</code>	The authentication failed due to a wrong password.
<code>PDF_E_UNKSECHANDLER</code>	The file uses a proprietary security handler, e.g. for a proprietary digital rights management (DRM) system.
<code>PDF_E_XFANEEDSRENDERING</code>	<p>The file contains unrendered XFA form fields, i.e. the file is an XFA and not a PDF file.</p> <p>The XFA (XML Forms Architecture) specification is referenced as an external document to ISO 32'000-1 (PDF 1.7) and has not yet been standardized by ISO. Technically spoken, an XFA form is included as a resource in a shell PDF. The PDF's page content is generated dynamically from the XFA data, which is a complex, non-standardized process. For this reason, XFA is forbidden by the ISO Standards ISO 19'005-2 (PDF/A-2) and ISO 32'000-2 (PDF 2.0) and newer.</p>

6.20.5 TPDFObjectType Enumeration

This enumeration is used to indicate a syntactical PDF object type as defined in the [PDF Reference 1.7](#), section "3.2 Objects".

Value	Description
<code>eTypeNull</code>	The PDF null object.
<code>eTypeBoolean</code>	A PDF object that represents a Boolean value (true or false).

eTypeInteger	A PDF numeric object that represents an integer number.
eTypeReal	A PDF numeric object that represents a real-valued number.
eTypeString	A PDF string object.
eTypeName	A PDF name object.
eTypeArray	A PDF array object.
eTypeDictionary	A PDF dictionary object.
eTypeStream	A PDF stream object.
eTypeIndirect	A PDF indirect object.

6.20.6 TPDFOrientation Enumeration

TPDFOrientation table

TPDFOrientation	
eOrientationUndef	Undefined
eOrientationTopLeft	Pages appear in columns, from bottom to top and right to left relative to page orientation.
eOrientationTopRight	Pages appear in columns, from bottom to top and left to right relative to page orientation.
eOrientationBottomRight	Pages appear in columns, from top to bottom and left to right relative to page orientation.
eOrientationBottomLeft	Pages appear in columns, from top to bottom and right to left relative to page orientation.
eOrientationLeftTop	Pages appear in rows, from right to left and bottom to top relative to page orientation.
eOrientationRightTop	Pages appear in rows, from left to right and bottom to top relative to page orientation.
eOrientationRightBottom	Pages appear in rows, from left to right and top to bottom relative to page orientation.
eOrientationLeftBottom	Pages appear in rows, from right to left and top to bottom relative to page orientation.

6.20.7 TPDFTextExtractConfiguration Enumeration

Value	Description
eTECBreakTextState	Start new text object if text state changes (font, font size, horizontal scaling). Set this flag if text state is important.
eTECBreakGraphicsState	Start new text object if graphics state changes (color). Set this flag if the color is important.
eTECBreakSpaceUnicode	<p>Start new text object if extracted text contains a blank Unicode (\t, non-breaking space, etc.). Do not set this flag if you need the RawString property.</p> <p>Example: If set, the text "Hello World" is extracted as "Hello" and "World". Otherwise, as "Hello World"</p>
eTECPosMergeSingleSpace	<p>Merge text tokens that are a single space width apart (displacement), insert space. Do not set this flag if you need the RawString property.</p> <p>Example: If set, the text objects "Hello" and "World" are extracted as "Hello World" if they are approximately one space width apart.</p>
eTECPosMergeMultiSpace	<p>Merge text tokens that are one or more space widths apart (horizontal displacement), but no more than 10'000 space widths. The merge is done by inserting multiple spaces. Do not set this option if you need the RawString property.</p> <p>Example: If set, the text objects "Hello" and "World" are extracted as "Hello World", where spaces are inserted to represent the distance of the objects.</p>

7 Version history

Some of the documented changes below may be preceded by a marker that specifies the interface technologies the change applies to. For example, [[C](#), [Java](#)] applies to the C and the Java interface.

7.1 Changes in versions 6.19–6.27

- **Update** license agreement to version 2.9
- **Improved** rounding of color return values from [GSGetStrokeColorRGB](#), [GSGetFillColorRGB](#), [GSGetStrokeColorCMYK](#) and [GSGetFillColorCMYK](#).

7.2 Changes in versions 6.13–6.18

- [[.NET](#), [C](#), [COM](#), [Java](#)] **Improved** extraction of document parts with missing End entry.

Interface [EmbeddedFile](#)

- [[.NET](#), [C](#), [COM](#), [Java](#)] **New** properties [AssociationRelationship](#), [Description](#) and [IsInitialDocument](#).
- [[.NET](#), [C](#)] **New** properties [CreationDate2](#) and [ModDate2](#).

7.3 Changes in versions 6.1–6.12

- [[Java](#)] **Changed** minimal supported Java language version to 7 [previously 6].
- [[PHP](#)] **Removed** all versions of the PHP interface.
- [[.NET](#)] **New** availability of this product as NuGet package for Windows, macOS and Linux.
- [[.NET](#)] **New** support for .NET Core versions 1.0 and higher. The support is restricted to a subset of the operating systems supported by .NET Core, see [Operating systems](#).
- [[.NET](#)] **Changed** platform support for NuGet packages: The platform “AnyCPU” is now supported for .NET Framework projects.

Interface [EmbeddedFile](#)

- [[.NET](#), [C](#), [COM](#), [Java](#)] **New** properties [AssociationRelationship](#), [Description](#) and [IsInitialDocument](#).
- [[.NET](#), [C](#)] **New** properties [CreationDate2](#) and [ModDate2](#).

7.4 Changes in version 5

- **New** additional supported operating system: Windows Server 2019.
- [[PHP](#)] **New** extension PHP 7.3 (non thread safe) for Linux.

7.5 Changes in version 4.12

- **New** HTTP proxy setting in the GUI license manager.
- **Improved** performance when extracting resources for certain documents.

7.6 Changes in version 4.11

- **New** support for reading PDF 2.0 documents.
- **Improved** repair of corrupt image streams.
- [PHP] **New** Interface for Windows and Linux. Supported versions are PHP 5.6 & 7.0 (non thread safe). The Pdf-Parser PHP interface is contained in the 3-Heights® PDF Tools PHP5.6 Extension and the 3-Heights® PDF Tools PHP7.0 Extension.
- [C] **Changed** 32-bit binaries on Windows that link to the API need to be recompiled due to a change of the used mangling scheme.
- [.NET, C, COM, Java, PHP] **New** [Interface DPartNode](#), [Interface DPartRoot](#), and [Interface PageRange](#) to allow the extraction of document parts from a PDF 2.0 or a PDF/VT document.

Interface Annotation

- [.NET, C, COM, Java] **New** property [QuadPoints](#) for extracting annotation quad points.

Interface Document

- [.NET, C, COM, Java, PHP] **New** property [DPartRoot](#) for extracting the document part information.

Interface DPartNode

- [.NET, C, COM, Java, PHP] **New** property [ChildrenCount](#) and method [Child](#) for extracting the child nodes of a document part node.
- [.NET, C, COM, Java, PHP] **New** property [DPM](#) to extract a node's document part metadata.
- [.NET, C, COM, Java, PHP] **New** property [PageRange](#) to extract a node's page range.

Interface DPartRoot

- [.NET, C, COM, Java, PHP] **New** property [NodeNameCount](#) and method [NodeName](#) for extracting the document parts' node name list.
- [.NET, C, COM, Java, PHP] **New** property [RecordLevel](#) for extracting the document parts' record level.
- [.NET, C, COM, Java, PHP] **New** property [RootNode](#) to access the root node in the document part hierarchy.

Interface PageRange

- [.NET, C, COM, Java, PHP] **New** properties [First](#) and [Last](#) to access the first and last page number in a page range.

Interface PDFObject

- [.NET, C, COM, Java, PHP] **New** property `TextStringValue` to extract the value of a string PDF object as a decoded string.

Interface Text

- [.NET, C, Java, PHP] **New** property `QuadPoints` for extracting the enclosing parallelogram.

7.7 Changes in version 4.10

- **Improved** robustness against corrupt input PDF documents.
- [C] **Clarified** Error handling of `TPdfStreamDescriptor` functions.
- **New** support of overlapping code ranges in font's ToUnicode tables (used for text extraction).

7.8 Changes in version 4.9

- **Improved** support for and robustness against corrupt input PDF documents.
- **Improved** repair of embedded font programs that are corrupt.
- **New** support for OpenType font collections in installed font collection.
- [C] **Changed** return value `pfGetLength` of `TPDFStreamDescriptor` to `pos_t`⁷.

Interface Document

- [.NET, C, Java] **New** method `OpenStream()`.

Interface Content

- [.NET, C, COM, Java] **Un-Deprecated** properties `ConvertPathToImage`, `PathImageAntiAlias`, `PathImageBGColor`, and `PathImageResolution`. The “paths as images” feature has been fully re-implemented with the rendering engine R2.

7.9 Changes in version 4.8

- **New** support for ToUnicode mappings that map characters to sequences of Unicodes (longer than 1). This includes special ligatures and surrogate pairs.
- **Improved** space width heuristic. This algorithm is required in order to estimate the width of a space in fonts that contain no space character. The space width is used to detect word breaks for example.
- **Improved** creation of annotation appearances to use less memory and processing time.
- **Added** repair functionality for TrueType font programs whose glyphs are not ordered correctly.

⁷ This has no effect on neither the .NET, Java, nor COM API

Interface Font

- [.NET, C, COM, Java] **New** property `Font.IsCID`.
- [.NET, C, COM, Java] **New** property `Font.HasUnicodes`.

Interface Document

- [.NET, C, COM, Java] **New** property `ProductVersion` to identify the product version.
- [.NET] **Deprecated** method `GetLicenseIsValid`.
- [.NET] **New** property `LicenseIsValid`.
